## SPRFMO SC10-Report

## Annex 10. Jack Mackerel Technical Annex

## 1. Introduction

1. This document and content are based on discussions and analyses conducted at the $10^{\text {th }}$ SPRFMO Scientific Committee (SC) meeting in 2022. The analyses updated the model and assumptions from the jack mackerel benchmark meeting (SCW14) and the report can be found on the meeting link (here). During SC10, the model was updated with new data, and subsequently accepted by the SC. Discussions at SC10 focused on the following topics:

- Review and update of data sets;
- Corrections to an error in the length metrics of the growth model used
- Change to the handling of selectivity and weight of the catch at age data for the offshore fleet in 2022.

2. A benchmark workshop for the jack mackerel stock assessment was completed in 2022 (SCW14). The main objective of the SCW14 workshop was to update the assessment with new data based on the updated aging criteria developed by Chile. These data included age compositions and weight-at-age in the catches of Chile and the offshore fleets, and in the acoustic surveys of Central and North of Chile. As a consequence of this update, a new maturity-at-age vector was estimated and a new value of natural mortality was derived ( $\mathrm{M}=0.28$ ). Overall, the changes caused by the new aging criteria led to the understanding of a faster-growing species that is earlier to mature
3. In addition, CPUE indices were updated to include a factor for increases in the efficiency of fishing effort ("effort creep"). The efficiency factor for the offshore CPUE index was estimated to be approximately $2.5 \%$ per year, whereas the factor was set at a very preliminary value of $1 \%$ per year for the Chilean and Peruvian CPUE indices (not based on a quantitative analysis). Reference points were also updated from previously-set interim levels. In addition, for the single-stock hypothesis, a new reference point has been derived for a limit biomass, $\mathrm{B}_{\mathrm{lim}}$, which was estimated at $8 \%$ of unfished spawning biomass. Compared to the most recent assessment using the 'old' age composition data, the perception of stock is relatively unchanged and is estimated to be well above $B_{\text {MSY, }}$ with fishing mortality is well below $F_{\text {MSY }}$.

## Scientific Name and General Distribution

4. The Chilean jack mackerel (Trachurus murphyi, Nichols 1920) is widespread throughout the South Pacific. It is found along the shelf and oceanic waters adjacent to Ecuador, Peru, and Chile, and across the South Pacific along the Subtropical Convergence Zone in what has been described as the "jack mackerel belt" that goes from the coast of Chile to New Zealand within a $35^{\circ}$ to $50^{\circ} \mathrm{S}$ variable band across the South Pacific

## Main Management Units

At least five management units of $T$. murphyi associated to distinct fisheries are identified in the SE Pacific: the Ecuadorian fishery, which is managed as part of a more general pelagic fishery within the Ecuadorian EEZ; the Peruvian fishery, which is managed as part of a jack mackerel, mackerel and sardine fishery directed exclusively for direct human consumption taking place almost entirely within the Peruvian EEZ; the northern and the central-southern Chilean fisheries which are managed as separate management units, with the northern fishery being mostly within the Chilean EEZ and the centralsouthern Chilean fishery which straddles the Chilean EEZ and the adjacent high sea; and, the purely high sea fishery which is a multinational fishery being managed entirely within the context of the SPRFMO. At present there is no directed fishery for T. murphyi in the central and western South Pacific and around New Zealand, where incidental catches are very small.

## Stock Structure

There are a number of competing stock structure hypotheses, and up to five and more separate stocks have been suggested: i) a Peruvian stock (northern stock) which is a straddling stock with respect to the high seas; ii) a Chilean stock (southern stock) which is also a straddling stock with respect to the high seas; iii) a central Pacific stock which exists solely in the high seas; iv) a southwest Pacific stock which exists solely in the high seas; v) and, a New Zealand-Australian stock which straddles the high seas and both the New Zealand and Australian EEZs. Regarding specifically the eastern and central South Pacific, the SPRFMO has identified the following four alternative stock structure working hypotheses: 1) jack mackerel caught off the coasts of Peru and Chile each constitute separate stocks which straddle the high seas; 2) jack mackerel caught off the coasts of Peru and Chile constitute a single shared stock which straddles the high seas; 3) jack mackerel caught off the Chilean area constitute a single straddling stock extending from the coast out to about $120^{\circ} \mathrm{W}$; and, 4) jack mackerel caught off the Chilean area constitute separate straddling and high seas stocks.

Accordingly, the Jack Mackerel Sub-group (JMSG) of the Science Working Group (SWG) of the SPRFMO at its 11th Session (SWG-11) carried out parallel assessments of the jack mackerel stock(s) in the Eastern South Pacific under the two main working hypotheses already identified. That is: jack mackerel caught off the coasts of Peru and Chile constitute a single shared stock which straddles the high seas (hypothesis 1); or that jack mackerel caught off the coasts of Peru and Chile each constitute separate stocks (the Peruvian or northern and the Chilean or southern stock) which straddle the high seas (hypothesis 2). In following up on the SWG-11 recommendations, the SPRFMO Commission at its 1st Commission Meeting requested the newly established Scientific Commission (SC) to continue the work on evaluating alternative hypotheses on jack mackerel stock population. Pending more conclusive findings on the stock population structure of jack mackerel, the 2 nd Commission meeting requested the SC to continue and expand the stock assessment work under both stock hypotheses considered in the 11th SWG Meeting, and this continues to be one of the main tasks undertaken at SC10.

## Fishery

The fishery for jack mackerel in the south-eastern Pacific is conducted by fleets from the coastal states (Chile, Peru and Ecuador), and by distant water fleets from various countries, operating beyond the EEZ of the coastal states.

The fishery by the coastal states is conducted by purse seiners. The largest fishery exists in Chile, where the fish are used for fish meal. In Peru, the fishery is variable from year to year. Here the fish are taken by purse seiners that also fish for other pelagic species (e.g., anchovy, mackerel, sardines). According to government regulations, the jack mackerel in Peru may only be used for human consumption. Ecuador constitutes the northern fringe of the distribution of jack mackerel. Here the fish only occur in certain years, when the local purse seiners may take substantial quantities (70,000 tons in 2011). Part of the catch is processed into fish meal but recently jack mackerel has been promoted to be used for human consumption.

The distant water fleets operating for jack mackerel outside the EEZs have been from a number of parties including Belize, China, Cook Islands, Cuba, European Union (Netherlands, Germany, Poland and Lithuania), Faroe Islands, Korea, Japan, Russian Federation, Ukraine and Vanuatu. These fleets consist exclusively of pelagic trawlers that freeze the catch for human consumption. In the 1980s a large fleet from Russia and other Eastern European countries operated as far west as $130^{\circ} \mathrm{W}$. After the economic reforms in the communist countries around 1990, the fishery by these countries in the eastern Pacific was halted. It was not until 2003 that foreign trawlers re-appeared in the waters outside the EEZs of the coastal states.

The jack mackerel fishery in Chilean and offshore waters is mono-specific. In the offshore fishery, the catch consists of $90-98 \%$ jack mackerel, with minor bycatch of chub mackerel (Scomber japonicus)
and Pacific bream (Brama australis). The available time series of jack mackerel catches in the southeastern Pacific by Member are shown in Table A10.1 with the catch summarised by fleets in Figure A10.1.

## Management

12. Jack mackerel were managed by coastal states beginning in the mid-1990s. National catch quotas for jack mackerel were introduced by Peru in 1995 and by Chile in 1999. Peru introduced a ban on the use of jack mackerel for fish meal in 2002. For the international waters, the first voluntary agreement to limit the number of fishing vessels was introduced in 2010. Catch limits for jack mackerel were established for the south-eastern Pacific starting from 2011.

## Information on the environment in relation to the fisheries

Important environmental events such as the El Niño effect of 2016 affect oceanographic dynamics. During such events, the depth of the $15^{\circ} \mathrm{C}$ isotherm and oxycline change significantly affecting the spatial distribution of jack mackerel and their availability in different regions (see for example the work of the Habitat Monitoring Working Group of the Scientific Committee as reported in previous meetings of the Scientific Committee). The extent that such changes affect the overall population productivity is unclear.

## Reproductive Biology

The main spawning season happens from October to December; however, spawning has been described from July to March. Gonadosomatic index and egg surveys have been used to determine the time of spawning.

## 2. Data used in the assessment

## Fishery Data

The catch data for the model represents a summation of catch values from various Members (Table A10.1) to form four "fleets", which are intended to be consistent with the gear and general areas of fishing (Figure A10.1). The summarised catches from each of these fleets are presented in Table A10.2.
16. Length data are available from all major fisheries both inside and outside the EEZs. Length distributions from Chile and the older international fleet were converted into age distributions using annual Chilean age-length keys. The more recent length composition data from China were converted to age compositions by applying Chilean age-length keys as compiled by quarter of the year and then aggregated (Table A10.3, Table A10.4, and Table A10.5). The EU provided age-length keys which were used to convert EU length distribution data to age. For Peruvian and Ecuadorian fisheries, length frequency data (Table A10.6) were used directly and fit within the model according to the specified growth curve.
17. In the benchmark workshop prior to SC10 (SCW14), a new Chilean ageing method was included into the assessment. This resulted in revisions to age composition data for both Chilean fleets, as well as the offshore fleet. In addition, several biological variables (weight, maturity, natural mortality) were reestimated and updated. Some detail on the revisions to the historical data and the validation approach can be found in the SCW11 report.

In the benchmark workshop SCW14, it was further agreed that a protocol should be developed to include self-sampling data from the Offshore fleet into the assessment. As introduced in meeting documents SC10-JM03 and SC10-JM04, the protocol stipulates that length-distributions from quarters that are not sampled in the observer program but that are covered in the self-sampling, will be included
into the assessment. For SC10 this meant that self-sampling data for 2021_Q2, 2022_Q2 and 2022_Q3 were included in the assessment data.
19. Several CPUE data series are used in the model, with changes in methodology to calculate the series introduced during SC4, SC6, SC7, SC9 and SC10. From SC10 onwards, the CPUE series include a factor that compensates for efficiency increases of fishing operations as estimated in global effort analysis (e.g. Rousseau et al 2019).
20. For the Chilean purse seiner fleet in the southern-central area, a "Generalized Linear Model" (GLM; McCullagh \& Nelder, 1989) approach has been used to standardise the CPUE. Here trip-based CPUE has been modelled as a linear combination of explanatory variables, with the goal of estimating a yeareffect that is proportional to jack mackerel biomass. Factors in the GLM included year, quarter, zone, and vessel hold capacity. Effort units were computed as the number of days spent fishing by each vessel. This CPUE series was revised during SC4 to exclude trips with no jack mackerel catches. This was preferred because it better reflected changes in management over time (particularly the introduction of vessel-level quotas starting in 2000). To account for changes in fleet behaviour arising from the changes in management, the revised CPUE series from the GLM was modelled with a catchability change in year 2000. In addition, an overall increase of technical efficiency of $1 \%$ per year has been included during SC10.
21. Prior to the 2018 assessment (SC6), Peru presented a CPUE abundance index derived from the industrial purse seine fleet. This fishery has a strong focus on anchoveta and other stocks such as chub mackerel (Scomber japonicus) and bonito (Sarda chiliensis). With increasing catch rates in those fisheries, the focus on jack mackerel shifted, and the CPUE index was deemed to be no longer indicative of jack mackerel biomass. This resulted in a lack of CPUE data between 2015 and 2017. Thus, for the 2018 assessment CPUE indicators were calculated based on artisanal and small-scale fleets. These fleets are and have been targeting jack mackerel on a regular basis, operating at a closer distance to the coast than the industrial fleets. Historical data on catch by haul capacity for the artisanal fleets were recovered beginning in 2000. A Generalised Additive Model, in which the dependent variable (catch per trip) is gamma-distributed using a log-link function, was applied by removing the operational (holding capacity) and temporal effects (year, month). The GAM combined data from both artisanal and industrial fleets, although concerns were raised about the accuracy of the historical data (e.g., from missing fleet identifiers) and thus there is a need for continued development. In addition, an overall increase of technical efficiency of 1\% per year has been included during SC10.

Up to the 2017 assessment (SC5), the European Union CPUE index (un-standardised), the Russian CPUE index (un-standardised) and the Chinese CPUE index (standardised with a GLM) were included as separate indices of exploitable biomass for the offshore fleet. However, it was noted that these fleets shared similar temporal and spatial dynamics and the European Union and Russian data were incorporated into a combined standardised offshore CPUE index in 2018 (SC6), with the Chinese CPUE kept separate. In 2019 (SC7), haul-by-haul data of China, EU, Korea, Vanuatu, and Russia were combined and standardised into a single Offshore CPUE time series (SC7-JM06 rev1). The standardisation procedure followed what had previously been done during SCW6. A GAM was fit to catch data with an offset of $\log$ (effort) assuming a negative binomial distribution. Vessel, month of the year, year, and El Niño effect (sea surface temperature anomaly) were taken as linear effects while two-dimensional smoothers were applied to correct for spatial effects. In SC9, the vessel explanatory variable was replaced by vessel contracting party, which resulted in CPUE indices that were similar in trend (SC9JM02). Note that the start year of the various offshore CPUE indices has varied over time. Originally, when the European Union CPUE index was separate from the Chinese and Russian CPUE indices (SC5), the index began in 2003. In SC6, when the Russian CPUE data was incorporated into the combined Offshore index, this index was taken as beginning in 2006. From 2019 (SC7), the combined Offshore CPUE index has been included in the stock assessment as an index for the period from 2008 to the
present. In addition, an overall increase of technical efficiency of $2.5 \%$ per year has been included during SC10.
23. In all standardised CPUE series (Table A10.7), no explicit correction for search time has been incorporated. In some products, such as the offshore CPUE, effort in weeks is taken rather than effort by day (of positive registrations) to account for searching time. However, the inability to consistently define and accurately measure searching time remains an issue.

In SCW14, advances in fishing technological efficiency (also termed "effort creep") were explicitly incorporated in the CPUE standardization process. As mentioned previously, annual effort creep value of $2.5 \%$ was thus applied to CPUE for the offshore fleet (details in SCW14-WD01). For the other CPUE series from Chile and Peru, no formal evaluations of technological advances had been conducted. As such, an interim level of $1 \%$ efficiency improvement was applied to each series. It was agreed that further analyses would be required to understand the model reaction to the effort creep factor and noted that at this stage this factor does not appear to have an important effect on model results. SCW14 further recommended specific studies to evaluate the potential efficiency improvements for these fleets, including the technical equipment (e.g., those under consideration by the SPRFMO Scientific Committee's Habitat Monitoring Working Group), and any other factors that could influence effective fishing effort.
Further, the lack of a defined protocol for CPUE standardisation has been noted. Development of CPUE standardisation guidelines has thus been identified as a priority to improve the quality of the assessment.

## Fisheries Independent Data

The Chilean jack mackerel research programme has included surveys using hydro-acoustics and the daily egg production method (DEPM). Acoustic estimates have been used as relative abundance indices. For the northern region ( N -Chile), data on acoustic biomass and numbers, and weights at age are available from 1984-1988, 1991, and 2006-2021. For the central-southern regions, these data are available from 1997 to 2009. In previous jack mackerel assessments, the acoustic survey in northern Chile was assigned the same selection-at-age curve as the northern Chile fishing fleet. However, given that the survey age composition data indicate that it catches younger ages than the fishing fleet, the SC6 considered it more appropriate to assign the survey its own selectivity.

Egg surveys (using DEPM) were conducted on an annual basis from 1999 to 2008 along the central zone of the Chilean coast in order to assess the biomass of the spawning stock. In addition, there are estimates of abundance and numbers-at-age for the central-southern regions based on DEPM for the years 2001, 2003, 2004, 2005, 2006, 2008. Egg survey results have been used as relative abundance indices in the models. Age composition data from the acoustic and DEPM Chilean surveys are shown in Table A10.8, Table A10.9, and Table A10.10.

In SC10, as mentioned previously, changes were made to the Chilean ageing methods. These resulted in updated historical age composition data for both Chilean surveys and the commercial catches.

The Peruvian jack mackerel research programme includes egg and larvae surveys and hydro-acoustic stock assessment surveys. Results of these egg and larvae surveys provide information on the spatial and temporal variability of jack mackerel larvae along the Peruvian coast beginning in 1966. Acoustic biomass estimates of jack mackerel were available beginning in 1983. As these surveys had Peruvian anchoveta as the target species, the data only covered the first 80 miles, and eventually 100 miles from the coast. Corrections to compensate for this partial coverage of acoustic biomass estimates of jack mackerel were made using an environmental index describing the potential habitat of this species based on available monthly data on SST, Sea Surface Salinity (SSS), water masses (WM), oxycline depth (OD) and chlorophyll (CHL). An alternative acoustic index for Peru was presented at SC3. This was constructed using backscatter information without converting the information to biomass estimates
using length-frequency data. This method was proposed to address the reduced quality of the available length-frequency data in recent years. This alternative series was included in the jack mackerel assessment in SC4, thus replacing the Peruvian acoustic series used in previous assessments. The last value provided for this series corresponds to 2013. The El Niño conditions in 2014 and 2015 affected the distribution of jack mackerel making them more dispersed and outside the area covered by the anchovy survey. Further work is needed to standardise and analyse the survey data to develop a reasonable index from the later data. The index has been retained in the current assessment and extends from 1985 to 2013.

Acoustic surveys, to estimate the biomass and distribution of jack mackerel, have also been conducted along the Chilean coast, inside and outside of the EEZ, using scientific vessels. Additionally, comprehensive acoustic surveys have been conducted from the Chilean commercial fleet. The time series of available acoustic estimates extends from 1984 to present day (intermittently, depending on the area). All abundance indices (fishery CPUE and survey) series used in the model are presented in Table A10.7.

## Biological Parameters

The maturity-at-age for jack mackerel in Chile was estimated by Leal et al. (2013) and has been updated by applying the new ageing criteria (SCW14-WD04) to the otoliths and histological maturity data collected between September 2011 and January 2012. Overall, the changes caused by the new aging criteria led to the understanding of a faster-growing species that is earlier to mature. Maturity-at-length was consistently observed with $L_{50}$ at about $22-23 \mathrm{~cm}$ fork length (FL). The maturity-at-age values, for the single/Southern stock and those for the far-north stock, are shown in Table A10.11.
To fit the length composition data from the far-north fleet, a growth curve was used to convert age compositions predicted by the model to predicted lengths, with the conversion occurring within the model. The values for the von Bertalanffy growth parameters are given in Table A10.12. It was noted in SC10 that the growth parameters reflected fish Total Length, whereas the data were in Fork Length. The parameters were since corrected. Ageing imprecision was previously acknowledged using an ageerror matrix, as shown in Table A10.13. However, because this matrix is based on expert judgement instead of empirical data, the discussions during SC4 led to selecting the final assessment model with this ageing error option turned off.

Mean weight-at-age is required for all fishing fleets and biomass indices in order to relate biomass quantities to the underlying model estimates of jack mackerel abundance (in numbers). The four weight-at-age matrices for the fishing fleets correspond to: Fleet 1 (northern Chile), Fleet 2 (centralsouth Chile), Fleet 3 (the far north fleet) and Fleet 4 (the offshore trawl fleet). These values are shown in Table A10.14, Table A10.15, Table A10.16, and Table A10.17.

For the Chilean fleets, the mean weight-at-age is calculated by year by taking the mean length-at-age in the catch and a length-weight relationship derived for the year. Before SC3, the same weight-at-age matrix was used for the Northern Chilean Fleet (Fleet 1) and the Southern Chilean Fleet (Fleet 2). Beginning in SC3, a weight-at-age matrix specific for Northern Chile has been applied. The method uses two information sources: the length-age keys and the parameters of the weight-at-length relationship from IFOP's monitoring programme of the Chilean fisheries. The information was separated into two zones which correspond to fishing areas (and acoustic surveys) that occur in Chile. Annual weight-atlength relationship was fitted to the data by each fleet independently, and these relationships were applied to mean length-at-age within each zone, resulting in the weights-at-ages seen in Table A10.14 and Table A10.15. The information covers the period 1974-2021; for earlier years the weight-at-age from 1974 was used.
35. For the far north fleet, mean weight-at-age is fixed for all years and was initially calculated from the time-invariant mean length-at-age estimated from the growth function (Table A10.12). The information covers the period from 1970 to present year (Table A10.16).
36. The weights-at-age for the offshore fleet are derived from EU age-length keys as well as age-length keys from the Chilean South-Central fleet. The EU reported both age, length, and weight data, allowing for weight-at-age to be reported for their catches based on observer programme data compiled in 2019. For China, Vanuatu, Russia and Korea, length-weight information is transformed using the Chilean fleet2 quarter-specific age-length keys (Table A10.17). Note that for most countries weight-at-length information is available. In some years however, including 2018, weight-at-length data from the Chinese fleet were missing, which resulted in using the length-weight relationship from the Chilean fleet 2. As of SCW14, due to the update in the Chilean ageing criteria, these weight-at-age data were updated for the time series beginning in 2015.

Historically, missing weight-at-age data were replaced with data from the previous year. In SCW14, it was recommended that those missing data be replaced with appropriate mean values by fleet instead. However, this has not been done during the SC10 assessment.
38. In SCW14, the Natural Mortality Tool (https://connect.fisheries.noaa.gov/natural-mortality-tool/) was used to derive values of M range from roughly 0.1 to 0.35 with a mode at 0.28 . The $L_{\infty}$ was assumed to be 80.4 cm , k was assumed at 0.16 and t0 at -0.356 . The value of 0.28 was used for the assessment in SC10. The estimated $M$ values are assumed to be the same for all ages and all years within the given stock (see Table A10.12).

## Data Sets

A full description of data sets used for the assessment of jack mackerel is in Annex 3 of the SC Data workshop 2015. Summaries of all data available for the assessment are provided in Table A10.18 and Figure A10.2.

## 3. The Assessment Model

40. A statistical catch-at-age model was used to evaluate the jack mackerel stocks. The JJM ("Joint Jack Mackerel Model") is implemented in AD Model Builder (ADMB) and considers different types of information, which correspond to the available data on the jack mackerel fishery in the South Pacific area from 1970 to 2021 (Table A10.18).
41. The JJM model is an explicitly age-structured model that uses a forward projection approach and maximum likelihood estimation to solve for model parameters. The operational population dynamics model is defined by the standard catch equation with various modifications such as those described by Fournier \& Archibald (1982), Hilborn \& Walters (1992) and Schnute \& Richards (1995). This model was adopted as the assessment method in 2010 after several technical meetings.

## JJM Developments

Since its adoption, the JJM model has been improved by participating scientists. The most notable changes have been options to include length composition data (and specifying or estimating growth) and the capability to estimate natural mortality by age and time (although this capability is not used). The model is flexible and permits the use of catch information either at age or size for any fleet, and explicitly incorporates regime shifts in population productivity.
43. The model consists of several components, (i) the dynamics of the stock; (ii) the fishery dynamics; (ii) observation models for the data; and (v) the procedure used for parameter estimation (including uncertainties).
49. Parameter estimation: The model parameters are estimated by maximising the log-likelihoods of the data plus the log of the probability density functions of the priors and smoothing penalties specified in the model. Estimation was conducted in a series of phases, the first of which used arbitrary starting values for most parameters. The model has been implemented and compiled in ADMB and its characteristics can be consulted in Fournier et al. (2012).

## Model Details

Parameters estimated conditionally are listed in Table A10.19. The most numerous of these involve estimates of annual and age-specific components of fishing mortality for each year and for each of the four fisheries identified in the model. Parameters describing population numbers at age 1 in each year (and years prior to 1970 to estimate the initial population numbers at ages 1-12+) were the second most numerous type of parameter.
51. Equations and specifications for the assessment model are given in Table A10.20 and Table A10.21. Table A10.22 contains the initial variance assumptions for the indices and the age and length compositions.
52. The treatment of selectivity patterns and how they are shared among fisheries and indices are given in Table A10.23 and Table A10.24 for the two stocks under the two-stock model configurations
(hypothesis 2), and Table A10.25 for the single-stock hypothesis (hypothesis 1). Selectivity for the Far North fleet was specified with a regime shift in 2002 under the two-stock hypothesis, while annual variations beginning in 1981 were specified for the same fleet under the single-stock hypothesis. Depending on the model configuration, some growth functions were employed inside the model to convert model-predicted age compositions to length compositions, in order to fit the model to the length composition data.
53. Equilibrium-based reference points are calculated within the jjm model. The model estimates values of MSY and F $_{\text {MSY }}$ using a Newton-Raphson minimization routine that finds the value of fishing mortality, given the terminal year relative catches (and selectivities-at-age) by fleet, and the terminal year weights-at-ages for each fleet, that maximizes catch. Since weights-at-age and "effective" selectivity change each year, these values can vary. MSY is thus defined as the maximum amount of catch that allows the remaining stock to generate sufficient recruitment to maintain the population at the same level. BMSY is taken as the long-term average of biomass fished under MSY. Between 2013 and 2021, a provisional $\mathrm{B}_{\text {MSY }}$ level of 5.5 million tons was applied. In SCW14, the interim management reference point for $B_{\text {MSY }}$ was revised to a ten-year average of the model-estimated $B_{\text {MSY }}$. A limit reference point $B_{\lim }$ (where B refers to spawning biomass) for the single-stock hypothesis was also developed during SCW14. Blim was defined as the spawning biomass level below which recruitment would likely be impaired. As such, there should be no fishing when the current spawning biomass is estimated to be below $\mathrm{B}_{\text {lim }}$. For jack mackerel, $\mathrm{B}_{\mathrm{lim}}$ was computed from the lowest ratio of historical spawning biomass relative to the most-recently-estimated unfished spawning biomass. In SCW14, this ratio was estimated to be $8 \%$ of the unfished spawning biomass.

## Models for Stock Structure Hypothesis

During SWG 11, two types of population structure were evaluated, and this was continued for subsequent evaluations. Beginning in 2020 (SC8), models under the one-stock hypothesis carry "h1" in front of the model number, models under the two-stock hypotheses carry " h 2 " in front of the model number.

## Description of Model Explorations

As SC10 was an update assessment, after the benchmark of SCW14, the main model explorations involved incrementally adding new data components relative to the model and data adopted from SCW14. These are labelled "h1_0.x" and "h2_0.x. where h1 and h2 represent the stock structure hypothesis and $x$ represents the number when a component was added (Table A10.26).

The rationale for the main updates and data revisions occurring through model configurations 0.00 to 0.10 has been explained in the "Data used in the assessment" section, earlier in this Annex.

Thereafter, Model 0.10 was renamed as Model 1.00. with an updated control file to reflect changes in selectivity for the current year, as was done in previous years.
During SC10, attention was brought to an analysis in the Peruvian National Report (SC10-Doc27). The analysis noted a mistake in the assessment, where growth parameters reflecting fish Total Length were applied to Fork Length data. The model was thus updated to correct the growth parameters $\left(\mathrm{L}_{\infty}=73.56\right.$; $\mathrm{L}_{0}=13.56$; SC10-Doc27) in Model 1.01.
In the most recent years of the fishery, there has been a notable northward shift in the distribution of fishing effort by the offshore fleet. This geographical shift has been associated with catches of smaller and younger fish. As a result, the model fit to the age composition data in these terminal years was poor. To address this, a second sensitivity was developed (Model 1.02). Age composition data in the terminal year has traditionally been down-weighted to reflect uncertainty in those data points. To better fit to the offshore data in the final year, the sample size was increased to be the same as that of earlier years. It should be noted that the overall weight of the offshore age composition data is quite
low relative to other data sources. In addition, more flexibility was added to the selectivity of the offshore fleet in 2022.
60. The final model used the Francis weights agreed upon by SCW14 for the multinomial age composition sample sizes, and these weights were not updated in this assessment. Also, the model took a precautionary approach to assessment and advice. It assumed low steepness ( $\mathrm{h}=0.65$ ) and used the most recent recruitment time-series (2001-2015), similar to assessments prior to SC5. Recruitment used in the forecast was taken directly from the assessment.
61. Beginning in SC9, efforts have been made to increase the reproducibility and transparency of the assessment process. A centralised repository for data submissions was created on Teams to facilitate ease of access. R scripts were developed to document the assessment update process. These scripts included code to 1) read in, analyse, and raise catch at age/length data, 2) incrementally update data files for the bridging exercise from the previous year's assessment to the new assessment, 3) update model files for model sensitivity runs, 4) conduct projections with the final model, and 5) create an HTML document for result presentation. Scripts for processing the data (1) are found in the jimData repository, whereas the assessment scripts can be found on the jim repository, in the assessment folder.

## 4. Results

Results from incrementally updating the data (Models 0.00 to 0.10 ) indicated a slight increase in biomass for recent years, with the largest change driven by the update to Peruvian CPUE data. Correcting the growth parameters (Model 1.01) had negligible impacts on the stock status. Similarly, adding flexibility to selectivity estimates in the offshore fleet (Model 1.02) improved fits to recent age composition data, but had negligible impact on stock status. Overall, the stock (or stocks; depending on the stock structure hypothesis used) shows continued increasing trends in biomass, similar to previous years.
63. An analytical retrospective analysis involves running the model multiple times, each time removing the final year of data (for five years). The retrospective analysis shows that Model h1_1.02 tended to slightly under-estimate SSB, with a Mohn's rho of -0.13 (Figure A10.3). Recruitment tended to be underestimated, with a Mohn's rho of -0.34 (Figure A10.4). The negative bias in recruitment is likely due to the fact that recruitment in recent years has been very high, and estimated recruitment in the final year reverts to a mean. Model h2_1.02 had a slight tendency to over-estimate SSB (Mohn's rho of 0.12 (south) and 0.21 (north); Figure A10.5) and under-estimate recruitment for the south (Mohn's rho of 0.11) and over-estimate the same for the north (Mohn's rho of 0.24; Figure A10.6).
64. An alternative to the analytical retrospective analysis, which is based on the current model formulation, the "historical retrospective analysis" instead compares quantities derived from assessments previously adopted by the SC. This indicates the year-to-year changes in estimates of stock trends and reference points. This analysis was only conducted on Model h1_1.02 (raw values for biomass found in Table A10.27; graphically visualised in Figure A10.7 and Figure A10.8). The results indicate that the current model formulation has a higher estimate of biomass relative to estimates from previous years. This was likely due to the revision in Chilean age data. Estimates of fishing mortality in recent years remain similar to those from previous SCs, although the current model estimates fishing mortality to be higher for historical years. Recruitment estimates appear mostly in line with those of previous models, with peaks in recruitment shifting by approximately two years. Overall, the trends appear consistent over time. Another interesting comparison to make is that of the management reference points (biomass (B) at maximum sustainable yield (MSY) and fishing mortality (F) at MSY; $B_{M S Y}$ and $F_{M S Y}$ respectively) estimated over the years. The updates to the age data in 2022, and subsequently the biological parameters, likely resulted in large changes to the reference points, $\mathrm{B}_{\text {MSY }}$ in particular (Figure A 10.8 ). Despite that, it is to be noted that stock status relative to those changed reference points remained largely the same for
recent years. Also, the stock has consistently been estimated as rebuilt since 2018, and not subject to overfishing since 2013, relative to the dynamically-estimated MSY reference points.
65. Fishery mean weights-at-age assumed for all models are shown in Figure A10.9, and those for the surveys are shown in Figure A10.10. Estimates of numbers-at-age from Model h1_1.02 are given in Table A10.28, and Model h2_1.02 results are in Table A10.29 (southern stock) and Table A10.30 (northern stock). Both models show similar good fits to the composition data (Figure A10.11, Figure A10.12, Figure A10.13, Figure A10.14, Figure A10.15, Figure A10.16, Figure A10.17, and Figure A10.18). The fits to age composition data from the surveys are given in Figure A10.19, Figure A10.20, Figure A10.21, Figure A10.22, Figure A10.23, and Figure A10.24. Models h1_1.02 and h2_1.02 fit the indices similarly (Figure A10.25 (h1), Figure A10.26 (h2 south), and Figure A10.27 (h2 north); they both fit well to the Chilean CPUE data and poorly to recent years of the offshore and Peruvian CPUE data, although the relative abundance estimates remained within the uncertainty bounds of the data. Whereas the models predicted higher relative abundance than was shown in the offshore CPUE data, they predicted lower relative abundance than was shown in the Peruvian CPUE data. Estimates of fishery mean age compositions are shown in Figure A10.28 (h1_1.02) and Figure A10.29 (h2_1.02), and survey mean age compositions are shown in Figure A10.30 (h1_1.02) and Figure A10.31 (h2_1.02). Both models fit poorly to data from the Central-South Chilean acoustic survey. Both models seem to estimate mean length composition data for the Far North fleet relatively poorly in recent years, as shown in Figure A10.32 and Figure A10.33. Selectivity estimates for the fishery and indices are shown over time in Figure A10.34, Figure A10.35, Figure A10.36, and Figure A10.37.

A summary of the time series stock status (spawning biomass, F, recruitment, total biomass) for the single-stock hypothesis (h1_1.02) is shown in Figure A10.38. It is noted that the biomass has been steadily increasing over the last decade, and is now above the $B_{\text {MSY }}$ management reference point. For the jack mackerel stock, with the current level at around $54 \%$ of what is estimated to have occurred had there been no fishing (Figure A10.41).
68. Under the 2-stock hypothesis (h2_1.02), conditions of the jack mackerel stock in its entire distribution range in the southeast Pacific shows a continued recovery since the time-series low in 2010. It is noted that under the two-stock model, the southern unit shows an increasing trend in biomass over the last decade (Figure A10.39), while the northern unit only shows an increase in biomass beginning in the middle of the last decade (Figure A10.40). The southern unit showed similar results to that of the singlestock hypothesis, although SSB was estimated slightly higher under the former scenario. Estimates of exploitation rate for the northern stock were comparable to recent years, remaining at relatively low levels (Figure A10.40). Figure A10.42 and Figure A10.43 show the current total biomass to be approximately $55 \%$ and $61 \%$ of unfished total biomass for the southern and the far north stocks respectively.

Fishing mortality rates at age (combined fleets) were high starting in about 1992 across the entire jack mackerel population, but have declined in the past years, regardless of stock structure hypothesis or designation (Table A10.31, Table A10.32, Table A10.33, Figure A10.38, Figure A10.39, and Figure A10.40). It should be noted that the low probability of $B_{2032}$ being greater than $B_{M S Y}$ under the $F_{M S Y}$ projection for model h1_1.05 is likely due to $B_{\text {MSY }}$ being set at the interim level, and not the modelestimated $B_{\text {MSY }}$. Within the period 2001-2015, the level of expected recruitment was lower than the alternatives although recruitment has increased in recent years to about the long-term average mean. The aforementioned period was used for projections but Model 1.02 uses the period 2001 to 2019 to
fit the stock recruitment curve for the southern/single stock. Time series of quantities derived by Model h1_1.02 are presented in Table A10.34, whereas those of Model h2_1.02 are in Table A10.35 (southern stock) and Table A10.36 (far north stock). Short, medium and long-term predictions for the stock(s) under different fishing mortalities are found under Table A10.37 (h1_1.02) and Table A10.38 (h2_1.02).

## 5. Management Advice

70. New data and indicators on the status of the jack mackerel stock suggest that conditions evaluated in detail from the last benchmark assessment (completed in 2022) are relatively unchanged. The population trend is estimated to be increasing. The indications of stock improvement (higher abundance observed in the acoustic survey in the northern part of Chile, better catch rates apparent in all fisheries for which data are available, and increase in average age in the Chilean fisheries) drive the increase.
71. Historical fishing mortality rates and patterns relative to the provisional biomass target are shown in Figure A10.38 for Model h1_1.02. Near-term spawning biomass is expected to increase from 14.3 million t in 2022 to 15.5 million $t$ in 2023 (with approximate $90 \%$ confidence bounds of 12.0 - 20.1 million $t$ ). Under the two-stock hypothesis, historical fishing mortality rates and patterns relative to the biomass targets estimated by Model h2_1.02 are shown in Figure A10.39 and Figure A10.40. Near-term spawning biomass is expected to increase from the 2022 estimate of 12.7 million $t$ to 13.8 million $t$ in 2023 for the southern stock (with approximate $90 \%$ confidence bounds of $10.0-19.2$ million $t$ ), and decrease from 1.5 million $t$ to 1.4 million $t$ for the far north stock (with approximate $90 \%$ confidence bounds of .98-2.1 million t).

Recent increases in the model-calculated $B_{M S Y}$ values (which is different from the constant $B_{M S Y}$ ) that are likely due to changes in selectivity of all fisheries combined, would imply an estimate of SSB at well over $50 \%$ over $B_{M S Y}$ for both the single-stock and the two-stock hypotheses.
73. Given current stock status, the fourth tier of the jack mackerel rebuilding plan (as defined in the SCW14 report) should be applied. This means that $F_{\text {MSY }}$ would be used as the basis for catch advice. However, this would result in a potential increase of over three times of last year's recommended catch. In line with the "adjusted Annex K" rebuilding plan (SC2), catch advice relative to the previous year can only increase by a maximum of $15 \%$. This results in advice of a 2023 catch level for jack mackerel within the entire jack mackerel range to be at or below 1,035,000t t.

Projections show a high likelihood of the biomass being above $B_{\text {MSY }}$ in 2024 even under the most conservative recruitment productivity scenario evaluated (h1_1.02.Is and h2_1.02.Is; Table A10.37 and Table A10.38). A re-evaluation of the rebuilding plan is recommended to analyse sustainable exploitation rates of the re-built jack mackerel stock.

## 6. Assessment Issues

75. Based on results from the 2022 benchmark workshop, assessment plans for the next benchmark should be developed several months prior so that data coordinators can configure alternatives and conduct a careful evaluation of all available information to best guide the Commission. One of the higher priority items for consideration continues to be the catch-at-age estimates (based on age-determinations being conducted from different labs) and mean body weights at age assumed in the model. Another priority for consideration is the development of guidelines for standardisation of CPUE indices and the collection of relevant data. In particular, evaluations of efficiency improvements for the Peruvian and Chilean fishing fleets were noted. Results of the data weighting and the retrospective pattern analysis also warrant further investigation.
76. The issue of evaluating sensitivities to the early fishery age composition data was raised. The SC noted that this might be a fruitful avenue for investigation in subsequent assessments, particularly since these
data (pre-1990) are less well-documented. Residual patterns in the age composition for the North Chilean fleet remain unresolved, and warrant further investigation as well.
77. The need for a closer evaluation comparing the performance of the model under the single-stock and two-stock hypotheses was noted, likely conducted using simulation and MSE.

Table A10.11. Jack mackerel sexual maturity by age used in the JJM models.

| Age (yr) | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 |
| :---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| Single / <br> Southern <br> Stock | 0.520 | 1.000 | 1.000 | 1.000 | 1.000 | 1.000 | 1.000 | 1.000 | 1.000 | 1.000 | 1.000 | 1.000 |
| Far North <br> Stock | 0.000 | 0.370 | 0.980 | 1.000 | 1.000 | 1.000 | 1.000 | 1.000 | 1.000 | 1.000 | 1.000 | 1.000 |

Table A10.12. Jack mackerel growth (von Bertalanffy) and natural mortality parameters used in JJM models.

| Parameter | Far North stock | Single / South stock |
| :--- | ---: | ---: |
|  |  |  |
| $L_{\infty}(\mathrm{cm})$ (Total length) | 73.56 | 73.56 |
| k | 0.16 | 0.16 |
| LO $(\mathrm{cm})$ | 13.56 | 13.56 |
| M (year-1) | 0.33 | 0.28 |

$L_{o}$ is the mean length at the recruitment age (1 yrs).

Table A10.13. Ageing error matrix of jack mackerel. Columns represent the observed ages, while the rows represent the true age. These data are not used in the stock assessment.

Table A10.18. Years and types of information used in the JJM assessment models.

| Fleet | Catch-at-age | Catch-at-length | Landings | CPUE | Acoustic | DEPM |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: |
| 1 North Chile <br> purse seine | $1980-2022$ | - | $1970-2022$ |  | Index: 1984-1988; | 1991; 2006-2021 |

${ }^{*}$ ) Are converted to age using age-length keys of central-southern area off Chile, the EU, and Russia.

Table A10.19. Symbols and definitions used for model equations.

| General Definitions | Symbol/Value | Use in Catch at Age Model |
| :--- | :---: | :--- |
| Year index: $i=\{1970, \ldots, 2022\}$ | $/$ |  |
| Fleets (f) and surveys $(\mathrm{s})$ | $f, s$ | Identification of information source |
| Age index: $j=\left\{1,2, \ldots, 12^{+}\right\}$ | $J$ |  |
| length index: $l=\{10,11, \ldots, 50\}$ | $L_{j}$ |  |
| Mean length at age | $c v$ |  |
| Variation coefficient of the length at age | $W_{t, j}$ |  |
| Mean weight in year $t$ by age $j$ | $M a x a g e$ | Selectivity parameterisation |
| Maximum age beyond which selectivity is constant | $M$ | Constant over all ages |
| Instantaneous Natural Mortality | $p_{j}$ | Definition of spawning biomass |
| Proportion females mature at age $j$ | $T$ |  |
| Ageing error matrix | $\Gamma$ | Transform from age to length |
| Proportion of length at some age | $T_{i}$ | Scales multinomial assumption about |
| Sample size for proportion in year $i$ |  | estimates of proportion at age |
| Survey catchability coefficient | $q^{s}$ | Prior distribution lognormal $\left.\mu_{q}^{s}, \sigma_{q}^{2}\right)$ |
| Stock-recruitment parameters | $R_{0}$ | Unfished equilibrium recruitment |
|  | $h$ | Stock-recruitment steepness |
|  | $\sigma_{R}^{2}$ | Recruitment variance |
| Unfished biomass | $\varphi$ | Spawning biomass per recruit when |
|  |  | there is no fishing |
| Estimated parameters |  |  |
| $\phi_{i}(\#), R_{0}, h, \varepsilon_{i}(\#), \mu^{f}, \mu^{s}, M, \eta_{j}^{s}(\#), \eta_{j}^{f}(\#), q^{s}(\#)$ |  |  |
| Note that the number of selectivity parameters estimated depends on the model configuration. |  |  |

Note that the number of selectivity parameters estimated depends on the model configuration.

Table A10.20. Variables and equations describing implementation of the Joint Jack Mackerel assessment model (JJM).

## Eq Description

1) Survey abundance index (s) by year. The
symbol $\Delta^{s}$ represents the fraction of the year when the survey occurs.
2) Catch biomass by fleet ( $f=1,2,3,4$ ), year(i) and age (j) /length (I)
(transformation from age to length composition. Fleet 3, FarNorth)
3) Proportion at age j, in year i

Proportion at length I, in year i
4) Initial numbers at age
5)
6)
7) Subsequent years (i>1970)
8)
9)
10) Year effect and individuals at age 1 and $\mathrm{i}=1958, \ldots, 2022$

## Symbol/Constraints Key Equation(s)

$I_{i}^{s}=q^{s} \sum_{j=1}^{12} N_{i j} W_{i j} S_{j}^{s} e^{-\Delta^{s} Z_{i j}}$

$$
I_{i}^{s}
$$

$$
\hat{C}_{i l}, \hat{C}_{i j}, \hat{Y}_{i}
$$

$\hat{C}_{i, j}^{f}=N_{i, j} \frac{F^{f}{ }_{i, j}}{Z^{f}{ }_{i, j}}\left(1-e^{-Z^{f}{ }_{i, j}}\right)$
$\widehat{\mathrm{Y}}^{f}{ }_{i}=\sum_{j=1}^{12+} \hat{C}_{i, j}^{f} w_{i, j}^{f}$
$\hat{C}_{i l}=\Gamma_{l j} \hat{C}_{i j}$
$\Gamma_{l, j}=\int_{j}^{j+1} e^{-\frac{1}{2 \sigma_{j}^{2}}\left(l-L_{j}\right)^{2}} d l$
$L_{j}=L_{00}\left(1-e^{-k}\right)+e^{-k} L_{j-1}$
$\sigma_{j}=c v L_{j}$
$p_{i j}^{f}=\frac{\hat{C}_{i j}^{f}}{\sum_{j} \hat{C}_{i j}^{f}} \quad p_{i j}^{s}=\frac{N_{i j} S_{j}^{s} e^{-\Delta^{s} Z_{i j}}}{\sum_{j} N_{i j} S_{j}^{s} e^{-\Delta^{s} Z_{i j}}}$
$P_{i l}=\frac{C_{i l}}{\sum_{l=10}^{50} C_{i l}}$

$$
j=1
$$

$N_{1970, j}=e^{\mu_{R}+\varepsilon_{1970}}$

Table A10.21 Specification of objective function that is minimised (i.e., the penalised negative of the log-likelihood).

| Eq | Likelihood /penalty component |  | Description / noted |
| :---: | :---: | :---: | :---: |
| 19) | Abundance indices | $L_{1}=0.5 \sum_{s} \frac{1}{c v_{s}^{2}} \sum_{i} \log \left(\frac{I_{i}}{\hat{I}_{i}}\right)^{2}$ | Surveys / CPUE indexes |
| 20) | Prior on smoothness for selectivities | $L_{2}=\sum_{l} \lambda_{2}^{l} \sum_{j=1}^{12}\left(\eta_{j+2}^{l}+\eta_{j}^{l}-2 \eta_{j+1}^{l}\right)^{2}$ | Smoothness (second differencing), Note: $I=\{s$, or $f\}$ for survey and fishery selectivity |
| 21) | Prior on recruitment regularity | $\begin{gathered} L_{3}=\lambda_{3} \sum_{i=1958}^{\text {final year }} \varepsilon^{2}{ }_{i} \\ \lambda_{3}=\frac{0.5}{\sigma_{R}^{2}} \end{gathered}$ | Influences estimates where data are lacking (e.g., if no signal of recruitment strength is available, then the recruitment estimate will converge to median value). |
| 22) | Catch biomass likelihood | $\begin{aligned} & L_{4} \\ & =0.5 \sum_{f} \frac{1}{c v_{f}^{2}} \sum_{i=1970}^{\text {final year }} \log \left(\frac{Y^{f}{ }_{i}}{\hat{Y}_{i}}\right)^{2} \end{aligned}$ | Fit to catch biomass in each year |
| 23) | Proportion at age/length likelihood | $L_{5}=-\sum_{v, i, j} n^{v} P_{i, j / l}^{v} \log \left(\hat{P}_{i, j / l}^{v}\right)$ | $v=\{s, f\}$ for survey and fishery age composition observations $P_{i, j / l}$ are the catch-at-age/length proportions n effective sample size |
| 24) | Dome-shaped selectivity | $\begin{aligned} & L_{6}=\lambda_{4} \sum_{j=6}^{12}\left(\ln S_{j-1}-\ln S_{j}\right)^{2} \\ & S_{j-1}>S_{j} \end{aligned}$ | (relaxed in final phases of estimation) |
| 25) | Fishing mortality regularity | F values constrained between 0 and 5 | (relaxed in final phases of estimation) |
| 26) | Recruitment curve fit | $\begin{aligned} & L_{7}=\lambda_{5} \sum_{j=1970}^{2015} \log \left(\frac{N_{i, 1}}{\tilde{R}_{i}}\right)^{2} \\ & \lambda_{5}=\frac{0.5}{\sigma_{R}^{2}} \end{aligned}$ | Conditioning on stock-recruitment curve over period 1970-2015. (Assessment models use the period 1970 to (present year - 3)) |
| 27) | Priors or assumptions | $R_{0}$ non-informative | $\sigma_{R}=0.6$ |
| 28) | Overall objective function to be minimised | $\dot{L}=\sum_{k} L_{k}$ |  |

Table A10.22. Coefficients of variation and sample sizes used in likelihood functions, with adjustments based on calculated Francis weights. Initial sample sizes are in parentheses.

| Abundance index | CV | Catch biomass likelihood | CV |
| :--- | :---: | :--- | :---: |

Table A10.23. Description of JJM model components and how selectivity was treated (two-stock hypothesis; Far North Stock).

| Item | Description | Selectivity assumption |
| :---: | :---: | :---: |
| Fisheries |  |  |
| 1) | Peruvian and Ecuadorian area fishery | Selectivity in the model under the two-stock hypothesis was estimated from length composition data (converted to age inside the model). Two regimes were considered - before and after 2002. This is a different assumption from the single-stock hypothesis, which has annual variations in selectivity between 1981 and 2022. |

| Index series |  |  |
| :--- | :--- | :--- |
| 2) | Acoustic survey in Peru | Assumed to be the same as in fishery 1) |
| 3) | Peruvian fishery CPUE | Assumed to be the same as in fishery 1) |

Table A10.24. Description of JJM model components and how selectivity was treated (two-stock hypothesis; Southern Stock).

| Item | Description | Selectivity assumption |
| :--- | :--- | :--- |
| Fisheries | Chilean northern area fishery | Estimated from age composition data. Annual variations were <br> considered since 1984 |
| 1) | Chilean central and southern <br> area fishery <br> Ostimated from age composition data. Annual variations were <br> considered since 1984. |  |
| 2) | Estimated from age composition data. Annual variations were <br> considered since 1980. Additional flexibility in selectivity was <br> allowed for 2022 to reflect a change in the fishing pattern. |  |
| 3) | Acoustic survey in central and | Estimated from age composition data. Two time-blocks were <br> considered 1970-2004; 2005-2009. |
| Index series | Estimated from age composition data. Selectivity changes <br> were implemented in 2012 and 2016. |  |
| 5) | Acoustic survey in northern |  |
| Chile | Central and southern fishery <br> CPUE | Assumed to be the same as 2) |
| 7) | Egg production survey | Estimated from age composition data. Two time-blocks were <br> considered 1970-2002; 2003-2008. |
| 8) | Offshore fleet (China, EU, <br> Korea, Russia, Vanuatu) CPUE | Assumed to be the same as 3) |

Table A10.25.Description of JJM model components and how selectivity was treated under the single-stock hypothesis.

| Item | Description | Selectivity assumption |
| :--- | :--- | :--- |
| Fisheries |  |  |
| 1) | Chilean northern area <br> fishery | Estimated from age composition data. Annual variations were <br> considered since 1984 |
| 2) | Chilean central and | Estimated from age composition data. Annual variations were <br> considered since 1984. |
| 3) | Peruvian and Ecuadorian <br> area fishery | Estimated from length composition data (converted to age inside <br> the model). Annual variations were considered since 1981 |
| 4) | Offshore trawl fishery | Estimated from age composition data. Annual variations were |
|  |  | considered since 1980. Additional flexibility in selectivity was <br> allowed for 2022 to reflect a change in the fishing pattern. |

| Index series |  |  |
| :---: | :---: | :---: |
| 5) | Acoustic survey in central and southern Chile | Estimated from age composition data. Two time-blocks were considered 1970-2004; 2005-2009. |
| 6) | Acoustic survey in northern Chile | Estimated from age composition data 2006-2016. Selectivity changes were implemented in 2015 and 2016 |
| 7) | Central and southern fishery CPUE | Assumed to be the same as 2) |
| 8) | Egg production survey | Estimated from age composition data 2001, 2003-2006, 2008. Two time-blocks were considered around 2003. |
| 9) | Acoustic survey in Peru | Assumed to be the same as 3) |
| 10) | Peruvian fishery CPUE | Assumed to be the same as 3) |
| 11) | Offshore fleet (Vanuatu, Russia, Korea, EU \& China) CPUE | Assumed to be the same as 4) |

Table A10.26. Systematic model progression from the 2021 assessment data to the agreed revised datasets for 2022. Note that the data file names corresponding to each model follow the same naming convention, but with the stock-structure hypothesis denoted as h1 for the single-stock and h2 for the two-stock (e.g., "0.01.dat" with "h1_0.01.ctl" and "h2_0.01.ctl).

| Model | Description |
| :---: | :---: |
| Models 0.x | Data introductions |
| 0.00 | Exact 2021 (single stock h1 and two-stock h2) model and data set (model 1.14) from benchmark SCW14. |
| 0.01 | As 0.00 but with revised catches through 2021 (currently still estimates) |
| 0.02 | As 0.01 but with updated 2021 fishery age composition data for N_Chile, SC_Chile, and Offshore_Trawl, and updated 2021 fishery length composition data for FarNorth |
| 0.03 | As 0.02 but with updated 2021 weight at age data for all fisheries and their associated CPUE indices |
| 0.04 | As 0.03 but replaced offshore CPUE up to 2021 |
| 0.05 | As 0.04 but with updated AcousN 2021 index, with associated age composition and weight at age |
| 0.06 | As 0.05 but with 2022 catch projections |
| 0.07 | As 0.06 but with updated 2022 fishery age composition data for N_Chile, SC_Chile, and Offshore_Trawl, and updated 2022 fishery length composition data for FarNorth |
| 0.08 | As 0.07 but with updated 2022 weight at age data for N_Chile, SC_Chile, and FarNorth fleets, and for their associated CPUE indices |
| 0.09 | As 0.08 but replaced SC_Chile_CPUE index (traditional absolute scaled CPUE by trip) |
| 0.1 | As 0.09 but replaced Peru_CPUE index |
| --------- | ------------- |
| Models 1.x | Updated Model and Sensitivities |
| 1.00 | As 0.10 but with updated model (selectivity changes, recruitment) to 2022; 0.10 data file |
| 1.01 | As 1.00 but with correct growth parameters to reflect FL (Linf=73.56; L0=13.56; SC10-Doc27 Peru National Report - ANJ) |
| 1.02 | As 1.01 but with added flexibility for selectivity in the offshore fleet |

Table A10.37. Summary results for the short, medium, and long-term predictions for Model h1_1.02.Is (single-stock hypothesis, low steepness, short timeseries). Note that "B" in all cases represents thousands of tonnes of spawning stock biomass, "P" represents probability as a percentage and $B_{M S Y}$ is taken to be the average $B_{M S Y}$ estimated over the last ten years.

| $F$ | $B_{2024}$ | $P\left(B_{2024}>B_{\text {MSY }}\right)$ | $B_{2028}$ | $P\left(B_{2028}>B_{\text {MSY }}\right)$ | $B_{2032}$ | $P\left(B_{2032}>B_{\text {MSY }}\right)$ | Catch 2023 (kt) | Catch 2024 (kt) |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| 0 | 16447 | 100 | 17978 | 100 | 17868 | 100 | 0 | 0 |
| $0.75 \times F_{2021}$ | 14813 | 100 | 13485 | 100 | 12541 | 97 | 764 | 844 |
| $F_{2021}$ | 14323 | 100 | 12409 | 99 | 11404 | 96 | 1006 | 1083 |
| $1.25 \times F_{2021}$ | 13856 | 100 | 11484 | 98 | 10462 | 93 | 1243 | 1305 |
| $F_{M S Y}$ | 10568 | 100 | 6908 | 68 | 6112 | 53 | 3120 | 2659 |

Table A10.38. Summary results for the short, medium, and long-term predictions for Model h2_1.02.Is (two-stock hypothesis). Note that " $B$ " in all cases represents thousands of tonnes of spawning stock biomass, " $P$ " represents probability as a percentage, and $B_{M S Y}$ is estimated dynamically within the model.
