Developing state-space biomass dynamics model with different time steps to assess the jumbo flying squid in Southeast Pacific Ocean

People's Republic of China

# Developing state-space biomass dynamics model with different time <br> steps to assess the jumbo flying squid in Southeast Pacific Ocean 

Gang Li, Yangming Cao, Xinjun Chen<br>Shanghai Ocean University

Shanghai, China

## Executive summary

The CPUEs of the Chinese squid-jigging fishery were standardized by the assumption of following a gamma distribution and used as relative abundance indices. Bayesian state-space surplus production models were employed to assess this stock from 2012 to 2021, taking into account annual and monthly data, as well as environmental conditions (El Niño and La Niña). Furthermore, we consider utilizing three different CPUEs in the assessment model due to the differences in operating methods and regions in Peru, Chile and China.

In the annual model, the stock has never been overfished and overfishing. In El Niño or La Niña years, $K$, MSY, and $B_{\text {MSY }}$ increased, while the intrinsic rate of increase (r) decreased during El Niño conditions but increased during Niña years.

In the monthly model, stock biomass exceeded $0.3 B_{\text {MSY }}$ but fell below $B_{\text {MSY }}$ in some months (mostly August-December during 2017-2021 except 2019). Fishing mortality remained much lower than $F_{\text {MSY }}$ regardless of environmental impacts, indicating no overfishing. The cause of this result still needs to be further studied.

The fishing mortality rate set at $F_{2021}(0.366 \sim 0.667)$ and $1.5 F_{2021-12}(0.046 \sim 0.073)$ were optimal for the future jumbo flying squid stock. In any given catch strategy, monthly biomass would rise and recover to $B_{\text {MSY. }}$. There is uncertainty in the actual process of population dynamics, which can be addressed by calculating the biomass that takes into account environmental impacts based on predicted Oceanic Niño Index. In addition, short-term management decision for jumbo flying squid should attempt to set various levels of monthly fishing mortality based on life history characteristics.

## 1. Introduction

The jumbo flying squid (Dosidicus gigas) is endemic to the eastern Pacific Ocean, with a distribution from California $\left(37^{\circ} \mathrm{N}\right)$ to southern Chile $\left(47^{\circ} \mathrm{S}\right)$, and to $140^{\circ} \mathrm{W}$ at the equator (Nigmatullin et al., 2001). It is one of the most abundant squids globally, harvested by domestic fleets from Chile and Peru, as well as Chinese industrial distant-water fishing fleets operating
in the high seas (Morales-Bojórquez and Pacheco-Bedoya, 2016). Owing to the environmental sensitivity of jumbo flying squid, climatic phenomena at various spatial and temporal scales (e.g. El Niño and La Niña) have significant impacts on distribution and resource abundance in the short term (Taipe, et al., 2001; Waluda et al., 2006). In addition, jumbo flying squid are characterized by fast growth rate and short life span, which makes the assessment and management of their populations challenging. Refining the time step of the model may help to handle the above characteristics in the stock assessment (Arkhipkin, et al., 2021). In this report, we attempted to use catch and effort data from the Chinese, Peruvian and Chilean fleets to develop Bayesian state-space surplus production model and environmental dependent model for assessing the jumbo flying squid.

## 2. Data

### 2.1 Catch and effort data

Total annual catch data of jumbo flying squid in the Southeast Pacific Ocean during 2012-2021 were derived from Food and Agriculture Organization (FAO) of United Nation (UN) database (www.fao.org/fishery/statistics/global-capture-production/query/en; accessed on 06/01/2023). Monthly catch and effort for Chile and Peru were provided by CALAMASUR, and others are from the SPRFMO annual report.

### 2.2 Abundance index data

(1) Peruvian fleets data

The abundance index (CPUE) data was directly from CALAMASUR.
(2) Chilean fleets data

The CPUE was calculated as follows:

CPUE $_{y, m}=$ Catch $_{y, m} /$ Effort $_{y, m}$
where Catch $_{y, m}$ is the total catch occurred in year $y$ and month $m$. Effort ${ }_{y, m}$ and $C P U E_{y, m}$ are the total fishing efforts (hauls) and CPUE, respectively.
(3) Asian fleets data

The CPUE of the Asian fleet was represented by Chinese squid fishing fleet. The data were from China Distant Water Fisheries Association, with field for fishing time (date), fishing area ( $0.25^{\circ}$ longitude $\times 0.25^{\circ}$ latitude) and yield. Nominal CPUE was defined as the fishing yield per day, in units of tons per day. Generalized Additive Model (GAM) is a common model for standardizing CPUE. The expression of GAM is as follows:
$\mathrm{g}\left(\mu_{i}\right)=\alpha+\sum f_{i} \times X_{i}+\varepsilon$
$\alpha$ is the intercept. $f_{i}$ is the related coefficient. $\varepsilon$ is the error term which is assumed to follow statistical distribution. $X_{i}$ is an independent variable including environmental factors (i.e. sea surface temperature (SST), concentration of chlorophyll-a (Chl_a), sea level anomaly (SLA), sea surface salinity (SSS) and Niño $1+2$ index), spatial-temporal factors (i.e. year, month, longitude, latitude, region (Figure 1)) and interaction terms. Variance inflation factor (VIF<10) indicated no serious multicollinearity between explanatory variables (Table 1).

The assumptions of the two types of GAM models were that $\log (C P U E)$ follows a normal distribution and CPUE follows a gamma distribution, respectively. For ease of modeling, the 0 value of nominal CPUE was removed.

Table 1. Variance inflation factor (VIF) among explanatory variables

| Year | Month | Region | Nino <br> $1+2$ <br> index | Latitude | Longitude | SST | SSS | Chl_a | SLA |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 1.59 | 2.08 | 4.56 | 1.61 | 7.69 | 5.11 | 4.83 | 1.81 | 1.16 | 1.68 |

Figure 1. Distribution of regions

### 2.3 Environmental data

Environmental data came from remote sensing satellite dataset in National Oceanic and Atmospheric Administration (NOAA) database (https://oceanwatch.pifsc.noaa.gov/doc.html, https://origin.cpc.ncep.noaa.gov/data/indices/; accessed on 06/01/2023).

## 3. Model development

### 3.1 Description of Bayesian state-space surplus production model

A complete operational surplus production model consists of two parts, i.e. dynamic model which describe the recruitment, growth and mortality of the stock and observation model which relates observation (e.g. CPUE or abundance index by scientific survey) to the stock biomass (Hilborn et al., 1992).

Pella and Tomlinson considered an extension of Schaefer model:
$B_{y+1}=\left(B_{y}+r B_{y}\left(1-\left(\frac{B_{y}}{K}\right)^{s}-C_{y, i}\right) e^{\mu_{y}}\right.$
where $B_{y}$ is the biomass at the beginning of year $y ; C_{y}$ is catch in year $y$ of $i ; \mu_{y}$ is process error which follows normal distribution (e.g. $\left.\mu_{y} \sim \operatorname{normal}\left(0, \sigma^{2}\right)\right), r$ is the intrinsic growth rate and $K$ is the capacity denoting the unexploited biomass size.

The form of observation model is as follows:
$I_{y, i}=q_{i} B_{y} e^{\varepsilon_{y}}$
where $i$ is different fleets, in order of Asia, Peru and Chile; $\mathrm{I}_{y, i}$ is the index of abundance for year $y$, fleet $i ; q_{i}$ is catchability coefficient of fleet $i ; \varepsilon_{y}$ is the observation error which follows normal distribution (e.g. $\varepsilon_{y} \sim \operatorname{normal}\left(0, \tau^{2}\right)$ ).

In this study, year-based and month-based Bayesian state-space Pella and Tomlinson's surplus production model was chosen to describe the fishery dynamic of jumbo flying squid in Southeast Pacific.

### 3.2 An environmental-dependent surplus production model

Cross-correlation analysis of the Niño $1+2$ index with CPUE showed a lag time of 4 months for impacts (Figure 2). Two categories for key parameters (i.e., r and K) were determined by sea surface temperature anomaly (SSTA) in the Niño $1+2$ area. Parameters $r_{-}$El_Niño and $K \_E l \_N i n ̃ o ~ w e r e ~ u s e d ~ t o ~ d e n o t e ~ r ~ a n d ~ K ~ f o r ~ c e r t a i n ~ y e a r s ~(m o n t h s) ~ w h e n ~ t h e ~ S S T A ~ w a s ~$ positive. Parameters $r_{-}$La_Niña and $K_{-}$La_Niña were used for the rest of the years (months) when the SSTA was negative (Figure 3 and 4).

Figure 2 Cross correlation function study on Niño $1+2$ index and CPUE

Figure 3 The annual SSTA of Niño 1+2 area and CPUE from year 2012 to 2022

Figure 4 The monthly SSTA of Niño 1+2 area and CPUE from month Jan 2012 to Dec 2022

### 3.3 Prior distribution

(1) Annual model

Setting appropriate prior distribution is primary in Bayesian paradigm. One base scenario and sensitivity analysis scenarios were set based on varied prior distribution for traditional model and environmental dependent model. In all scenarios, the standard deviations of process and observation error follow inverse gamma distribution (Table 2 and 3).

Table 2. The prior distributions of parameters for annual traditional surplus production model

| Parameter | Basic Scenario | Sensitivity 1 |
| :---: | :---: | :---: |
| $r$ | uniform $(0.1,3)$ | dlnorm $(0.2,0.8)$ |
| $K$ | uniform $(1200,25000)$ | uniform $(1200,10000)$ |
| $q_{1,} q_{2,}, q_{3}$ | uniform $(0,1)$ | uniform $(0,1)$ |
| $s$ | uniform $(0.1,3)$ | uniform $(0.5,1.5)$ |
| $\mathrm{B}_{2012} / K$ | uniform $(0.1,1)$ | uniform $(0.1,1)$ |
| $\tau^{2}$ | inverse gamma $(0.001,0.001)$ | inverse gamma $(0.001,0.001)$ |
| $\sigma^{2}$ | inverse gamma $(0.001,0.001)$ | inverse gamma $(0.001,0.001)$ |

Table 3. The prior distributions of parameters for annual environmental-dependent model

| Parameter | Basic Scenario | Sensitivity 1 |
| :---: | :---: | :---: |
| $r_{-}$El_Niño | uniform $(0.1,3)$ | dlnorm $(0.2,0.8)$ |
| $K_{-}$El_Niño | uniform $(1200,25000)$ | uniform $(1200,10000)$ |
| $r_{-} \mathrm{La}$ _Niña | uniform $(0.1,3)$ | dlnorm $(0.2,0.8)$ |
| $K_{-} \mathrm{La} \_$Niña | uniform $(1200,25000)$ | uniform $(1200,10000)$ |
| $q_{1,} q_{2}, q_{3}$ | uniform $(0,1)$ | uniform $(0,1)$ |
| $s$ | uniform $(0.1,3)$ | uniform $(0.5,1.5)$ |
| $\mathrm{B}_{2012} / K$ | uniform $(0.1,1)$ | uniform $(0.1,1)$ |

(2) Monthly model

Adjusting the model to assess in monthly steps, the prior distribution of $r$ needs to be $1 / 12$ of that in the annual model (Table 4 and 5).

Table 4. The prior distributions of parameters for monthly traditional surplus production

| model |  |
| :---: | :---: |
| Parameter | Basic Scenario |
| $r$ | uniform $(0,0.25)$ |
| $K$ | uniform $(1200,25000)$ |
| $q_{1,} q_{2}, q_{3}$ | uniform $(0,1)$ |
| $s$ | uniform $(0.1,3)$ |
| $\mathrm{B}_{2012-1} / K$ | uniform $(0.1,1)$ |
| $\tau^{2}$ | inverse gamma $(0.001,0.001)$ |
| $\sigma^{2}$ | inverse gamma $(0.001,0.001)$ |

Table 5. The prior distributions of parameters for monthly environmental-dependent model

| Parameter | Basic Scenario |
| :---: | :---: |
| $r_{-}$El_Niño | uniform $(0,0.25)$ |
| $K_{-}$El_Niño | uniform $(1200,25000)$ |
| $r_{-}$La_Niña | uniform $(0,0.25)$ |
| $K_{-}$La_Niña | uniform $(1200,25000)$ |
| $q_{1}, q_{2}, q_{3}$ | uniform $(0,1)$ |
| $s$ | uniform $(0.1,3)$ |

| $\mathrm{B}_{2012-1} / K$ | uniform $(0.1,1)$ |
| :---: | :---: |
| $\tau^{2}$ | inverse gamma $(0.001,0.001)$ |

### 3.4 Posterior distribution and convergence test

Monte Carlo Markov Chain (MCMC) is used to estimate model parameters and biological reference points. The estimation process is carried out in Winbugs. Three chains are used and each chain calculates a total of 50,000 times. The first 10,000 times were discarded and the rest values are reserved once every 20 times. The initial value of each chain is shown in Table 6, 7, 8 and 9.

Convergence of the MCMC samples to the posterior distribution was checked by monitoring the trace of three chains of each parameter. Gelman and Rubin (1992) diagnostics was also examined.

Table 6. The initial value of different MCMC chains in annual traditional model

| Parameter | $K$ | $r$ | $q_{1,} q_{2,} q_{3}$ | $\mathrm{~B}_{2012} / K$ | $s$ | $\tau^{2}$ | $\sigma^{2}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Chain 1 | 4000 | 0.5 | 0.04 | 0.5 | 0.5 | 0.1 | 0.1 |
| Chain 2 | 7000 | 0.7 | 0.05 | 0.7 | 0.7 | 0.1 | 0.1 |
| Chain 3 | 10000 | 1.0 | 0.06 | 1.0 | 1.0 | 0.1 | 0.1 |

### 3.5 Biological reference points estimation

The biological reference points are essential for figuring out the stock status and giving management advises. The biological references were calculated as follows:

$$
\begin{align*}
& B_{M S Y}=K(s+1)^{(-1 / s)}  \tag{5}\\
& F_{M S Y}=r(1-1 /(s+1))  \tag{6}\\
& M S Y=B_{M S Y} \times F_{M S Y}  \tag{7}\\
& B_{\text {lim }}=0.3 \times B_{M S Y} \text { (ICES, 2021) } \tag{8}
\end{align*}
$$

### 3.6 Projections

For the annual traditional model, $F_{2021}$ as the baseline to set the multi-level fishing mortality coefficient. $X F_{2021}$ and $F_{\text {MSY }}$ were used as fishing mortality rates for 2022-2023 to estimate the biomass, annual total allowable catch (TAC), respectively. In this study, $X$ was set as $0.75,1$, 1.25 and 1.5 to do the projections.

For the monthly traditional model, $F_{2021-12}$ as the baseline to set the multi-level fishing mortality coefficient. $X F_{2021-12}$ and $F_{\mathrm{MSY}}$ were used as monthly fishing mortality rates in 2022 to estimate the biomass, monthly total allowable catch (TAC) for 2022, respectively. $X$ was also set as $0.75,1,1.25$ and 1.5 .

## 4. Results

### 4.1 Generalized Additive Model

Four best GAMs based on different time scales and statistical distributions were shown in Table 10. Comparing the results of the cross-validation tests for the GAM models (Table 11), case Gamma Distribution_Year and Gamma Distribution_Month were found to have higher Spearman correlations and lower root mean squared error (RMSE), and thus may be more suitable for CPUE standardization of jumbo flying squid. The annual standardized CPUE and nominal CPUE followed almost identical trend, but differed from the year effect $\left(\mathrm{R}^{2}=0.48\right.$, Figure 5). The year effect was used as an abundance index in the stock assessment model. Trends in monthly standardized CPUE, nominal CPUE and monthly effects converged, with the exception of a few months, particularly in August and December 2013 (Figure 6).

Table 10. Best GAM selected based AIC values

### 4.2 Estimates of parameters in annual model

The significant difference between prior distribution and posterior distribution indicated that the data in the model provided sufficient information to dominate the form of posterior distribution in all scenarios (Figure 7 and 8). According to the results of the test, all the model runs in each scenario were converged.

The estimates of parameters for traditional surplus production model were shown in Table 12. For the base scenario, the mean and the median value of parameters $r, K, q_{1}, q_{2}, q_{3}, s, \sigma^{2}, \tau^{2}$ and $\mathrm{B}_{2012} / K$ were 1.37 and $1.26,5.18$ and 3.74 million tons, 0.004 and $0.004,0.034$ and $0.029,0.016$ and $0.013,1.28$ and $1.15,0.016$ and $0.007,0.424$ and $0.398,0.59$ and 0.60 , respectively. For the sensitivity analysis scenario, the mean and the median value of parameters $r, K, q_{1}, q_{2}, q_{3}, s$ and $\mathrm{B}_{2012} / K$ were 1.33 and $1.16,4.60$ and 4.17 million tons, 0.005 and $0.004,0.036$ and 0.030 , 0.017 and $0.014,0.97$ and $0.96,0.016$ and $0.007,0.419$ and $0.394,0.55$ and 0.56 , respectively.

The estimates of parameters for environmental dependent model were shown in Table 13. For the base scenario, the mean and the median value of parameters $r_{-}$El_Niño, $r_{-}$La_Niño, $K_{-}$El_Niño, $K_{-}$La_Niña, $q_{1}, q_{2}, q_{3}, s, \tau^{2}, \sigma^{2}$ and $\mathrm{B}_{2012} / K$ were 1.16 and $1.01,1.47$ and $1.40,9.03$ and 7.57 million tons, 8.06 and 6.83 million tons, 0.003 and $0.002,0.024$ and $0.019,0.011$ and $0.009,0.97$ and $0.76,0.017$ and $0.007,0.421$ and $0.393,0.54$ and 0.56 , respectively. For the sensitivity analysis scenario, the mean and the median value of parameters $r_{-} \mathrm{El}$ Niño, $r_{-}$La_Niño, $K_{-} E l \_N i n ̃ o, ~ K_{-}$La_Niña, $q_{1}, q_{2}, q_{3}, s, \tau^{2}, \sigma^{2}$ and $\mathrm{B}_{2012} / K$ were 1.06 and $0.89,1.34$ and $1.16,5.80$ and 5.72 million tons, 5.21 and 5.09 million tons, 0.003 and $0.003,0.027$ and $0.022,0.012$ and $0.01,0.96$ and $0.94,0.017$ and $0.007,0.426$ and $0.398,0.57$ and 0.59 , respectively.

### 4.3 Estimates of parameters in monthly model

The results of the prior and posterior distributions were shown in Figures 9 and 10.
The estimates of parameters for traditional surplus production model were shown in Table 14. For the base scenario, the mean and the median value of parameters $r, K, q_{1}, q_{2}, q_{3}, s, \sigma^{2}, \tau^{2}$ and $\mathrm{B}_{2012-1} / K$ were 0.18 and $0.20,4.53$ and 3.27 million tons, 0.006 and $0.006,0.034$ and 0.030 , 0.004 and $0.003,1.87$ and $1.91,0.114$ and $0.106,15.7$ and $15.6,0.56$ and 0.55 , respectively.

The estimates of parameters for environmental dependent model were shown in Table 15. For the base scenario, the mean and the median value of parameters $r_{-}$El_Niño, $r_{-}$La_Niño, $K_{-}$El_Niño, $K_{-}$La_Niña, $q_{1}, q_{2}, q_{3}, s, \tau^{2}, \sigma^{2}$ and $\mathrm{B}_{2012-1} / K$ were 0.15 and $0.16,0.16$ and 0.17 , 8.68 and 6.96 million tons, 5.96 and 4.61 million tons, 0.004 and $0.003,0.022$ and $0.017,0.002$ and $0.002,1.87$ and $1.94,0.111$ and $0.102,15.6$ and $15.5,0.58$ and 0.57 , respectively.

### 4.4 Biological reference points

Three biological reference points were estimated. The results from annual traditional model were shown in Table 16. For the base scenario, the mean and median value of MSY were 1.26 and 1.05 million tons. The mean and median value of $B_{\text {MSY }}$ were 2.60 and 1.92 million tons. The mean and median value of $F_{\text {MSY }}$ were 0.64 and 0.61 . For the sensitivity analysis scenario, the mean and median value of MSY were 1.17 and 1.01 million tons. The mean and median value of $B_{\text {MSY }}$ were 2.28 and 2.07 million tons. The mean and median value of $F_{\text {MSY }}$ were 0.62 and 0.56 .

The results from annual environmental dependent model were shown in Table 17. For the base scenario, the mean and median value of MSY_El_Niño and MSY_La_Niña were 1.56 and 1.16 million tons, 1.83 and 1.43 million tons, respectively. The mean and median value of $B_{\mathrm{MSY}}$ El_Niño and $B_{\mathrm{MSY}}$ La_Niña were 4.29 and 3.60 million tons, 3.82 and 3.23 million tons, respectively. The mean and median value of $F_{\mathrm{MSY}}$ El_Niño and $F_{\mathrm{MSY}}$ La_Niña were 0.46 and $0.38,0.58$ and 0.51 , respectively. For the sensitivity analysis scenario, the mean and median value of MSY_El_Niño and MSY_La_Niña were 1.23 and 1.05 million tons, 1.41 and 1.25 million tons, respectively. The mean and median value of $B_{\text {MSY }}$ El_Niño and $B_{\text {MSY_L_L_Niña were }} 2.86$ and 2.82 million tons, 2.57 and 2.50 million tons, respectively. The mean and median value of $F_{\text {MSY_El_Niño }}$ and $F_{\text {MSY_L_ }}$ Niña were 0.50 and $0.42,0.63$ and 0.55 , respectively.

The results from monthly traditional model were shown in Table 18. For the base scenario, the mean and median value of MSY were 0.29 and 0.20 million tons. The mean and median value of $B_{\text {MSY }}$ were 2.54 and 1.82 million tons. The mean and median value of $F_{\text {MSY }}$ were 0.115 and 0.119 .

The results from monthly environmental dependent model were shown in Table 19. For the base scenario, the mean and median value of MSY_El_Niño and MSY_La_Niña were 0.47 and 0.33 million tons, 0.33 and 0.22 million tons, respectively. The mean and median value of $B_{\text {MSY_ }}$ El_Niño and $B_{\text {MSY_L_L }}$ La_Niña were 4.87 and 3.88 million tons, 3.34 and 2.57 million tons, respectively. The mean and median value of $F_{\text {MSY }}$ El_Niño and $F_{\text {MSY_L }}$ La_Niña were 0.097 and $0.099,0.101$ and 0.103 , respectively.

### 4.5 Stock status

The temporal trends of Bratio ( $B / B_{\mathrm{MSY}}$ ) and Fratio ( $F / F_{\mathrm{MSY}}$ ) in different scenarios showed similar patterns. According the Kobe plot of the annual model, the stock being overfishing or overfished had never happened since 2012, and the probability of the stock being healthy in the terminal year in traditional model were $59.2 \%$ and $51 \%$ (Figure 11). The probability of the stock being healthy in the terminal year in environmental dependent model were $59.5 \%$ and 61.1\% (Figure 12).

The month-based traditional model provided a more detailed reflection of population dynamics. Biomass was greater than $B_{\mathrm{lim}}$ in all months, but some months were less than $B_{\mathrm{MSY}}$, i.e., Jan 2011-Feb 2011, Jul 2017-Jan 2018, Jul 2018-Apr 2019, Aug 2020-Dec 2020 and Aug 2021-Dec 2021 (Figure 13a). During these months, the stock is in a state of cautionary. It is necessary to reduce fishing mortality to prevent overfished (Figure 14). Moreover, the fishing mortality for all months were much lower than the $F_{\text {MSY }}$ (Figure 13b). The biomass of the monthly environmental dependent model fluctuated even more dramatically (Figure 15). There is a $37.4 \%$ probability that the biomass was less than $B_{\text {MSY }}$ in the terminal month (Figure 16). The results of the monthly traditional model showed that the biomass in 2018 was less than $B_{\mathrm{MSY}}$, and also in 2021 in the monthly environmental model (Figure 17).

### 4.6 Projections

For a species like jumbo flying squid, which has a short life cycle and is highly susceptible to environmental impacts, it is more reliable to develop a short-term management measure. The status of jumbo flying squid in 2022-2023 was predicted. Biomass would decline when fishing mortality exceeded $F_{2021}$ (Table 20 and 21). Under the fishing mortality rate of $F_{2021}$, the base and sensitivity scenarios of the traditional model predicted $B_{2023} / B_{\text {MSY }}$ of 1.05 and 1.14 , TAC of 932 and 929 kt in 2022, 920 and 930 kt in 2023, respectively. Under the fishing mortality rate of $1.25 F_{2021}$, the base and sensitivity scenarios of the environment dependent model predicted
$B_{2023} / B_{\mathrm{MSY}}$ of 1.11 and 1.03 , TAC of 1404 and 1141 kt in 2022, 1133 and 1050 kt in 2023, respectively.

The projection from the monthly model showed an upward trend in biomass that slowed with increasing fishing mortality (Figure 18). Under the fishing mortality rate of $1.5 F_{2021-12}$, the traditional model and environment dependent model predicted the biomass in the last month of 2022 were high at 2034 kt and 3148 kt , at which point the TAC would be 144 kt and 141 kt , respectively (Table 22 and 23). TAC in 2022 were 1578 kt and 1527 kt , respectively.
