# SPRFMO SC7-Report <br> Annex 8. Jack Mackerel Technical Annex Rev1 ${ }^{1}$ 

## 1. Introduction

This document and content are based on discussions and analyses conducted at the Scientific Committee (SC) meeting in 2019. The analyses updated the model and assumptions from SC6 (the last full assessment in 2018), and a preferred model configuration was agreed upon at the workshop. A summary of discussions during the workshop can be found on the SC7 meeting webpage. The model was updated with new data, and subsequently accepted at the SC7 meeting. Discussions at SC7 focused on the following topics:

- Review and update of data sets;
- Assumptions on selectivity and catchability for the fisheries and surveys;
- The need for safeguards for weight-at-age data templates to reduce the likelihood of erroneous inputs.

## Scientific Name and General Distribution

The Chilean Jack mackerel (Trachurus murphyi, Nichols 1920) is widespread throughout the South Pacific, along the shelf and oceanic waters adjacent to Ecuador, Peru, and Chile, and across the South Pacific along the Subtropical Convergence Zone in what has been described as the "jack mackerel belt" that goes from the coast of Chile to New Zealand within a $35^{\circ}$ to $50^{\circ} \mathrm{S}$ variable band across the South Pacific.

## Main Management Units

At least five management units of $T$. murphyi associated to distinct fisheries are identified in the SE Pacific: the Ecuadorian fishery, which is managed as part of a more general pelagic fishery within the Ecuadorian EEZ; the Peruvian fishery, which is managed as part of a Jack mackerel, mackerel and sardine fishery directed exclusively for direct human consumption taking place almost entirely within the Peruvian EEZ; the northern and the central-southern Chilean fisheries which are managed as separate management units, with the northern fishery being mostly within Chilean EEZ and the central-southern Chilean fishery which straddles the Chilean EEZ and the adjacent high sea; and, the purely high sea fishery which is a multinational fishery being managed entirely within the context of the SPRFMO. At present there is no directed fishery for T. murphyi in the central and western South Pacific and around New Zealand, where, if any, incidental catches are very small.

## Stock Structure

There are a number of competing stock structure hypotheses, and up to five and more separate stocks have been suggested: i) a Peruvian stock (northern stock) which is a straddling stock with respect to the high seas; ii) a Chilean stock (southern stock) which is also a straddling stock with respect to the high seas; iii) a central Pacific stock which exists solely in the high seas; iv) a southwest Pacific stock which exist solely in the high seas; v) and, a New Zealand-Australian stock which straddles the high seas and both the New Zealand and Australian EEZs. Regarding specifically the eastern and central South Pacific, the SPRFMO has identified the following four alternative stock structure working hypotheses: 1) Jack mackerel caught off the coasts of Peru and Chile each constitute separate stocks which straddle the high seas; 2) Jack mackerel caught off the coasts of Peru and Chile constitute a single shared stock which straddles the high seas; 3) Jack mackerel caught off the Chilean area constitute a single straddling stock

[^0]extending from the coast out to about $120^{\circ} \mathrm{W}$; and, 4) Jack mackerel caught off the Chilean area constitute separate straddling and high seas stocks.

Accordingly, the Jack Mackerel Sub-group (JMSG) of the Science Working Group (SWG) of the SPRFMO at its 11th Session (SWG-11) carried out parallel assessments of the Jack mackerel stock(s) in the Eastern South Pacific under the two main working hypotheses already identified. That is: that Jack mackerel caught off the coasts of Peru and Chile each constitute separate stocks (Peruvian or northern and Chilean or southern stocks - hypothesis 1) which straddle the high seas; and, that Jack mackerel caught off the coasts of Peru and Chile constitute a single shared stock (hypothesis 2) which straddles the high seas. In following up on the SWG-11 recommendations, the SPRFMO Commission at its 1st Commission Meeting requested the newly established SC to continue the work on evaluating alternative hypotheses on Jack mackerel stock population. Pending more conclusive findings on the stock population structure of Jack mackerel, the 2 nd Commission meeting requested the SC to continue and expand the stock assessment work under both stock hypotheses considered in the 11th SWG Meeting, and this continues to be one of the main tasks undertaken at SC7.

## Fishery

The fishery for Jack mackerel in the south-eastern Pacific is conducted by fleets from the coastal states (Chile, Peru and Ecuador), and by distant water fleets from various countries, operating beyond the EEZ of the coastal states.

The fishery by the coastal states is done by purse seiners. The largest fishery exists in Chile, where the fish are used for fish meal. In Peru, the fishery is variable from year to year. Here the fish are taken by purse seiners that also fish for other pelagic species (e.g., anchovy, mackerel, sardines). According to government regulations, the Jack mackerel in Peru may only be used for human consumption. Ecuador constitutes the northern fringe of the distribution of Jack mackerel. Here the fish only occur in certain years, when the local purse seiners may take substantial quantities ( 70,000 tons in 2011). Part of the catch is processed into fish meal but recently Jack mackerel has been promoted to be used for human consumption.

The distant water fleets operating for Jack mackerel outside the EEZs have been from a number of parties including Belize, China, Cook Islands, Cuba, European Union (Netherlands, Germany and Lithuania), Faroe Islands, Korea, Japan, Russian Federation, Ukraine and Vanuatu. These fleets consist exclusively of pelagic trawlers that freeze the catch for human consumption. In the 1980s a large fleet from Russia and other Eastern European countries operated as far west as $130^{\circ} \mathrm{W}$. After the economic reforms in the communist countries around 1990, the fishery by these countries in the eastern Pacific was halted. It was not until 2003 that foreign trawlers re-appeared in the waters outside the EEZ of the coastal states.

The Jack mackerel fishery in Chilean and offshore waters is mono-specific. In the offshore fishery, the catch consists for $90-98 \%$ of Jack mackerel, with minor bycatch of chub mackerel (Scomber japonicus) and Pacific bream (Brama australis). The available time series of Jack mackerel catches in the southeastern Pacific by country are shown in Table A8.1 with the catch summarised by fleets in Figure A8.1.

## Management

Jack mackerel were managed by coastal states beginning in the mid-1990s. National catch quotas for Jack mackerel were introduced by Peru in 1995 and by Chile in 1999. Peru introduced a ban on the use of Jack mackerel for fish meal in 2002. For the international waters, the first voluntary agreement on limitation of the number of vessels was introduced in 2010. Starting from 2011, catch limits for Jack mackerel were established for all countries fishing in the convention area in the south-eastern Pacific.

## Information on the environment in relation to the fisheries

Important environmental events (e.g., the 2016 El Niño) affect oceanographic dynamics. During such events, the depth of the $15^{\circ} \mathrm{C}$ isotherm and oxycline changed significantly affecting the spatial distribution of Jack mackerel and their availability in different regions. The extent that such changes affect the overall population productivity is unclear.

## Reproductive Biology

The main spawning season happens from October to December; however, spawning has been described to occur from July to March. Gonadosomatic index and eggs surveys have been used to determine the time of spawning.

## 2. Data used in the assessment

## Fishery Data

The catch data for the model sum values from various countries (Table A8.1), and form four "fleets", which are intended to be consistent with the gear and general areas of fishing (Figure A8.1). The catches from each of these fleets are presented in Table A8.2.

Length data are available from all major fisheries both inside and outside the EEZs. Length distributions from Chile and the older international fleet were converted into age distributions using annual Chilean age-length keys. The more recent length composition data from China and EU were converted to age compositions by applying Chilean age-length keys as compiled by quarter of the year and then aggregated (Table A8.3, Table A8.4, and Table A8.5). In some years, including 2018 and 2019, the EU provided age-length keys which were used to convert EU length distribution data to age. For Peruvian and Ecuadorian fisheries, length frequency data (Table A8.6) were used directly and fit within the model according to the specified growth curve.

Several CPUE data series are used in the model, with some changes introduced during SC6 and SC7. For the Chilean purse seiner fleet, a "Generalized Linear Model" (GLM; McCullagh \& Nelder, 1989) approach was used to standardise the CPUE. Here CPUE was modelled as a linear combination of explanatory variables with the goal to estimate a year-effect that is proportional to Jack mackerel density. Factors in the GLM included year, quarter, zone, and vessel hold capacity. Effort units were computed as the number of days spent fishing by each vessel. This CPUE series was revised during SC4 to exclude trips with no Jack mackerel catches. This was preferred because it better reflects changes in management over time (particularly the introduction of vessel-level quotas starting in 2000). To account for changes in fleet behaviour arising from the changes in management, the revised CPUE series from the GLM was modelled to have a catchability change in year 2000.

Up to 2018, Peru had been using a CPUE abundance index derived from the industrial purse seine fleet. This fishery has a strong focus on anchoveta and other stocks such as chub mackerel (Scomber japonicus) and bonito (Sarda chiliensis). With increasing catch rates in those fisheries, the focus on Jack mackerel shifted, and the CPUE index was deemed no longer indicative of Jack mackerel biomass. This resulted in a lack of CPUE data between 2015 and 2017 for previous assessments. Thus, in 2018, a change was introduced. CPUE indicators were calculated based on artisanal and small-scale fleets. These fleets are and have been targeting the Jack mackerel on a regular basis, operating at a closer distance to the coast than the industrial fleets. Historical data on catch by haul capacity for the artisanal fleets were recovered beginning in 2000. A Generalised Additive Model, in which the dependent variable (catch per trip) is gamma-distributed using a log-link function, was applied by removing the operational (holding capacity) and temporal effects (year, month). The GAM combined data from both artisanal and industrial fleets, although concerns were raised about the accuracy of the historical data (e.g., from missing fleet identifiers) and thus there is a need for continued development.

Until 2017, both the European CPUE index (un-standardised), the Russian CPUE index (un-standardised) and the Chinese CPUE index (standardised with a GLM) were included as separate indices of exploitable biomass for offshore fleet. The Russian data were incorporated into a combined standardised offshore CPUE index in 2018, with the Chinese CPUE kept separate. In 2019, haul-by-haul data of China, EU, Korea, Vanuatu, and Russia were combined and standardised into a single Offshore CPUE time series (SC7-JM06 rev1). The standardisation procedure followed what had previously been done during SCW6. A GAM was fit to catch data with an offset of log(effort) assuming a negative binomial distribution. Vessel, month of the year, year, and El Niño effect (sea surface temperature anomaly) were taken as linear effects while two-dimensional smoothers were applied to correct for spatial effects. The resultant combined Offshore CPUE index included in the 2019 stock assessment was from 2008 to 2018, whereas the 2018 Offshore CPUE index was from 2006 to 2017. It was noted that these fleets share similar temporal and spatial dynamics.

In all standardised CPUE series, no explicit correction for search time has been incorporated. In some products, such as the offshore CPUE, effort in weeks is taken rather than effort by day (of positive registrations) to account for searching time. However, the inability to consistently define and accurately measure searching time remains an issue. Further, the lack of a defined protocol for CPUE standardisation was noted, and it was agreed that the development of CPUE standardisation guidelines should be a priority to improve the quality of the assessment. These guidelines should include some guidance on the best types of models to use (e.g., GLM vs. GAM), and explore how best to define search time. Considerations should also be made to include flexibility for future improvements and revisions.

## Fisheries Independent Data

The Chilean Jack mackerel research programme has included conducting surveys using hydroacoustics and the daily egg production method (DEPM). Acoustic estimates and egg survey results are used as relative abundance indices. For the northern region (N-Chile) data on acoustic biomass and number and weight at age are available annually from 2006 to 2019. For the central-southern regions, these data are available from 1997 to 2009. In previous Jack mackerel assessments, the acoustic survey in northern Chile was assigned the same selection-at-age curve as the northern Chile fishing fleet; however, given the survey age composition data indicate that it catches younger ages than the fishing fleet, the SC6 considered it more appropriate to assign the survey its own selectivity. To estimate the abundance of the spawning stock, egg surveys (through the DEPM) were conducted on an annual basis from 1999 to 2008 along the central zone of the Chilean coast. In addition, there are estimates of abundance and numbers-at-age for the central-southern regions based on DEPM for the years 2001, 2003, 2004, 2005, 2006, 2008. Age composition data for the acoustic and DEPM Chilean surveys are shown in Table A8.7, Table A8.8, and Table A8.9.

The Peruvian Jack mackerel research programme includes egg and larvae surveys and hydro-acoustic stock assessment surveys. Results of these egg and larvae surveys provide information on the spatial and temporal variability of Jack mackerel larvae along the Peruvian coast from 1966 to-date. During SC3, a new series of acoustic biomass was provided by Peru for years 1986-2013. This series represented estimations based on the assumption of shifts in habitat area and its impact over traditional estimations. Acoustic biomass estimates of Jack mackerel are available from 1983 to-date. Because these surveys have the Peruvian anchoveta as the target species, the data only covered the first 80 miles, and eventually 100 miles from the coast. Corrections to compensate for this partial coverage of acoustic biomass estimates of Jack mackerel were being made by using an environmental index describing the potential habitat of this species based on available monthly data on SST, Sea Surface Salinity (SSS), water masses (WM), oxycline depth (OD) and chlorophyll (CHL), since 1983 to the present.

An additional alternative acoustic index for Peru was presented at SC3. This was constructed using backscatter information without converting the information to biomass estimates using lengthfrequency data. This method was proposed to address the reduced quality of the available lengthfrequency data in recent years. This alternative series was included in the Jack mackerel assessment in SC4, thus replacing the Peruvian acoustic series used in previous assessments. The last value provided for this series corresponds to 2013. The El Niño conditions in 2014 and 2015 affected the distribution of Jack mackerel making them more dispersed and outside the area covered by the anchovy survey. Further work is needed to standardise and analyse the survey data to develop a reasonable index from these data. This index has been retained in the current assessment.

Acoustic surveys, to estimate the biomass and distribution of Jack mackerel, have also been conducted along the Chilean coast, inside and outside of the EEZ and in the Peruvian EEZ, using scientific vessels. Additionally, comprehensive acoustic surveys have been conducted from the Chilean commercial fleet. The time series of available acoustic estimates extends from 1985 to 2013 (depending on the area). All abundance indices (fishery CPUE and survey) series used in the model are presented in Table A8.10.

## Biological Parameters

The maturity-at-age assumed for Jack mackerel was based on a Chilean study (Leal et al. 2012). The application of these results reduced the age at first reproduction by about one year, to 2-3 years from the 3-4 years used in the assessment a few years ago. Maturity at length was consistently observed with L50 at about 23 cm fork length (FL). The maturity-at-age values, and those for the far-north stock, are shown in Table A8.11.

To fit the length composition data from the far-north fleet, a growth curve was used to convert age compositions predicted by the model to predicted lengths, with the conversion occurring within the model. The values for the von Bertalanffy growth parameters are given in Table A8.12. Ageing imprecision is acknowledged using an age-error matrix, as shown in Table A8.13. However, because this matrix is based on expert judgement instead of actual data, the discussions during SC4 led to selecting the final assessment model with this ageing error option turned off.

Mean weight-at-age is required for all fishing fleets and biomass indices in order to relate biomass quantities to the underlying model estimates of Jack mackerel abundance (in numbers). The four weight at-age matrices for the fishing fleets correspond to: fleet 1 (northern Chile), fleet 2 (central-south Chile), fleet 3 (the far north fleet) and fleet 4 (the offshore trawl fleet). These values are shown in Table A8.14, Table A8.15, Table A8.16, and Table A8.17.

In Chile, the mean weight-at-age is calculated by year by taking the mean length at age in the catch and a length-weight relationship of the year. Before SC3, the same weight at age matrix was used for the Northern Chilean Fleet (Fleet 1) and Southern Chilean Fleet (Fleet 2). Beginning in SC3, a weight-at-age matrix specific for Northern Chile has been applied. The method uses two information sources: the length-age keys and the parameters of the weight-at-length relationship from IFOP's monitoring programme of the Chilean fisheries. The information was separated into two zones which correspond to fishing areas (and acoustic surveys) that occur in Chile. Annual weight-at-length relationship was fitted to the data by each fleet independently, and these relationships were applied to mean length-atage within each zone (Table A8.14 and Table A8.15). The information covers the period 1974-2019; for earlier years the weight-at-age from 1974 was used.

In Peru, mean weight-at-age is calculated by year taking the invariant mean length-at-age estimated from the growth function (Table A8.12) and the length-weight relationship of the year. The information covers the period 1970-2019 (Table A8.16).

The weights-at-age for the offshore fleet are derived from EU age-length keys as well as age-length keys from the Chilean South-Central fleet. The EU reported both age, length, and weight data, allowing for weight-at-age to be reported for their catches based on observer programme data compiled in 2018.

For China, Vanuatu, Russia and Korea, length-weight information is transformed using the Chilean fleet2 quarter-specific age-length keys (Table A8.17). Note that for most countries weight-at-length information is available. In some years however, including 2018, weight-at-length data from the Chinese fleet were missing, which resulted in using the weight-length relationship from the Chilean fleet 2 .

It was noted during SC7 that these weight-at-age data showed unusual patterns and warranted further investigation. For example, the reported weights of age-2 and age-3 fish for the Chilean Central-South and Offshore fleets in 2015 were anomalously higher relative to those historically reported. A similar anomaly emerged in the 2018 weight-at-age data for the Offshore fleet. A decision was made to use an average of the previous and the subsequent years for those aforementioned years and fleets. This interim measure was taken in lieu of a more in-depth look at those data, which will be discussed at the next benchmark assessment.

Estimates of natural mortality are derived from Pauly's method, using the Gili et al. (1995) growth function for Chile and the Dioses (2013) growth function for Peru. The estimated $M$ values are assumed to be the same for all ages and all years within the given stock (see Table A8.12).

## Data Sets

A full description of data sets used for the assessment of Jack mackerel is in Annex 3 of the SC Data workshop 2015. A summary list of all data available for the assessment is provided in Table A8.18.

## 3. The Assessment Model

A statistical catch-at-age model was used to evaluate the Jack mackerel stocks. The JJM ("Joint Jack Mackerel Model") is implemented in ADMB and considers different types of information, which corresponds to the available data of the Jack mackerel fishery in the South Pacific area from 1970 to 2019 (Table A8.18).

The JJM model is an explicit age-structured model that uses a forward projection approach and maximum likelihood estimation to solve for model parameters. The operational population dynamics model is defined by the standard catch equation with various modifications such as those described by Fournier and Archibald (1982), Hilborn and Walters (1992) and Schnute and Richards (1995). This model was adopted as assessment method in 2010 after several technical meetings.

## JJM Developments

Since its adoption, the JJM model has been improved by participating scientists. The most noted changes have been options to include length composition data (and specifying or estimating growth) and the capability to estimate natural mortality by age and time. The model is now more flexible and permits the use of catch information either at age or size for any fleet, and explicitly incorporates regime shifts in population productivity.

The model can be considered to consist of several components, (i) the dynamics of the stock; (ii) the fishery dynamics; (ii) observation models for the data; and (v) the procedure used for parameter estimation (including uncertainties).

Stock dynamics: recruitment is considered to occur in January while the spawning season is considered as an instantaneous process at mid-November. The population's age composition considers individuals from 1 to $12+$ years old for the single stock hypothesis (hypothesis 2 ) as well as for the southern stock in the two-stock hypothesis (hypothesis 1), while for the northern stock (hypothesis 1 ) 1 to $8+$ years old are considered. In all cases a stochastic Beverton-Holt relationship (Beverton \& Holt 1957) between stock and recruitment is included. The survivors follow the age-specific mortality composed by fishing mortalities at-age by fleet and the natural mortality, the latest one supposed to be constant over time and ages. The model is spatially aggregated except that the fisheries are geographically distinct. The
initial population is based on an equilibrium condition and occurs in 1958 (12 years prior to the model start in 1970) in the case of the single stock (hypothesis 2) and in the southern stock in the case of the two-stock hypothesis (hypothesis 1), while in the northern stock equilibrium condition occurs in 1962 (8 years prior to the model start in 1970).

Fishery dynamics: The interaction of the fisheries with the population occurs through fishing mortality. Fishing mortality is assumed to be a composite of several processes - selectivity (by fleets), which describes the age-specific pattern of fishing mortality; catchability, which scales fishing effort to fishing mortality; and effort deviations, which are a random effect in the fishing effort - fishing mortality relationship. The selectivity is non-parametric and assumed to be fishery-specific and time-variant. The catchability is index-specific, and there are nine abundance indexes. For some of the indices, time variations in catchability and / or selectivity have been considered.

Observation models for the data: There are five data components that contribute to the log-likelihood function - the total catch data, the age-frequency data, the length-frequency data and the abundance indices data.

The probability distributions for the age and length-frequency proportions are assumed to be approximated by multinomial distributions. Sample size is specified to be different by gear but mostly constant over years. For the total catch by fishery (4) and abundance indices (9), a log-normal assumption has been assumed with constant CV; the CV for the fisheries is 0.05 whereas the CVs for the abundance indices depend on the index. Beginning in 2018, as discussed in SC4 and agreed upon in SCW6, the Francis T1.8 weighting method (Francis 2011) is used to assign weighted sample sizes for age-frequency data. The same data weights from SC6 were used for the SC7 update.

Parameter estimation: The model parameters are estimated by maximising the log-likelihoods of the data plus the log of the probability density functions of the priors and smoothing penalties specified in the model. Estimation was conducted in a series of phases, the first of which used arbitrary starting values for most parameters. The model has been implemented and compiled in ADMB and its characteristics can be consulted in Fournier et al. (2012).

## Model Details

Parameters estimated conditionally are listed in Table A8.19. The most numerous of these involve estimates of annual and age-specific components of fishing mortality for each year from 1970-2019 and each of the four fisheries identified in the model. Parameters describing population numbers at age 1 in each year (and years prior to 1970 to estimate the initial population numbers at ages 1-12+ and $1-8+$ ) were the second most numerous type of parameter.

Equations and specifications for the assessment model are given in Table A8.20 and Table A8.21. Table A8.22 contains the initial variance assumptions for the indices and age and length compositions.

The treatment of selectivity and how they are shared among fisheries and indices are given in Table A8.23 and Table A8.24 for the two stocks under the two-stock model configurations, and Table A8.25 for the single-stock hypothesis. Selectivity for the FarNorth fleet was specified with a regime shift in 2002 under the two-stock hypothesis, while annual variations beginning in 1981 were specified under the single-stock hypothesis. Depending on the model configuration, some growth functions were employed inside the model to convert model-predicted age compositions to length compositions, in order to fit the model to the length composition data.

## Models for Stock Structure Hypothesis

During SWG 11, two types of population structure were evaluated, and this was continued for subsequent evaluations. Models under the two-stock hypotheses carry the same naming convention but have the letters " N " or "S" appended to designate split-stock model runs (for North and South stock structure hypothesis).

## Description of Model Explorations

As SC7 was an update assessment, the only model explorations involved incrementally adding new data components relative to last year's Jack mackerel model (Model 1.5 from SC6). These are labelled "Mod0.x" where x represents the number when a component was added (Table A8.26).

The rationale for the main updates and data revisions occurring through model configurations 0.00 to 0.18 has been explained in the "Data used in the assessment" section, earlier in this Annex. The data exercise concluded with Model 0.18.

Thereafter, Model 0.18 was renamed as Model 1.00 . with an updated control file to reflect changes in selectivity for the current year, as was done in previous years. Given that this was an update assessment, alternate model configurations and sensitivities were not explored at this meeting, and Model 1.00 was adopted. The most salient features of this model configuration, agreed by SC7, are outlined below.

Notably, the final model used the Francis weights agreed upon by SC6 for the multinomial age composition sample sizes, and these weights were not updated in this assessment. Also, the model took a precautionary approach to assessment and advice. It assumed low steepness ( $h=0.65$ ) based on the most recent recruitment time-series (2000-2015), similar to assessments prior to SC5, proposing a precautionary approach to assessment and advice. Furthermore, the recent strong recruitment estimate for 2016 was found to be greatly different from the previous years, and not confirmed at a population-wide level. As such, for the purposes of a more precautionary projection, the decision was made to use the lower $95 \%$ confidence interval for 2016 recruitment value.

## 4. Results

Results comparing the impact of new data (Models $0.00-0.18$ ) show that updating the fishery composition data in particular resulted in a change of recruitment trends in recent years. Changing the anomalous weights at ages resulted in no change to the perception of stock status. Other major data updates include the incorporation of the Chinese index into the Offshore CPUE index, as mentioned previously, which resulted in a more optimistic outlook on the stock.

The analytical retrospective analysis (which involves running the model multiple times, each time removing the final year of data, done for five years) shows that the time series of recruitment and SSB have a slight tendency to be over-estimated relative to the next year's estimates when more data were added. Further, as more data are accumulated, the magnitude of recruitment estimates can change (Figure A8.2).

An alternative to the analytical retrospective analysis, which is based on the current model formulation, the "historical retrospective analysis" instead compares quantities derived from assessments previously adopted by the SC (raw values for biomass found in Table A8.27; graphically visualised in Figure A8.3 and Figure A8.4). This indicates the year-to-year changes in estimates of stock trends and reference points. Results indicate that the current model formulation is consistent in the most recent years for biomass and fishing mortality. The recruitment comparison shows that high recruitment of the 2016 year class that was estimated in 2017 is no longer evident from the most recent assessment (Figure A8.3). Downward revision of SSB was further driven by an update in the Chinese CPUE and a change in assumption on fleet selectivity, allowing free estimation of F -at-age in recent years compared to more rigid assumptions in the 2017 model configuration.

Assumed fishery mean weight-at-age assumed for all models are shown in Figure A8.5. Estimates of numbers-at-age from the model are given in Table A8.28. The fishery age and length composition fits are shown in Figure A8.6, Figure A8.7, Figure A8.8, and Figure A8.9. The fits to age composition data from the surveys are given in Figure A8.10 and Figure A8.11. This model fit the indices well (Figure A8.12). Fits to the fishery and survey mean age compositions are shown in Figure A8.13 and Figure

A8.14 respectively. Fits to mean length compositions for the Far North fleet are shown in Figure A8.15. Selectivity estimates for the fishery and indices are shown over time in Figure A8.16.

A summary of the time series stock status (spawning biomass, F, recruitment, total biomass) for the single-stock hypothesis is shown in Figure A8.17. As in past years, the biomass can be projected forward based on the estimated recruits to evaluate the impact of fishing under four scenarios with different recruitment (and hence productivity) assumptions. This can be informative to distinguish environmental effects relative to direct fishing impacts. For the Jack mackerel stock, fishing appears to be a major cause of the population trend, with the current level at around $48 \%$ of what is estimated to have occurred had there been no fishing (Figure A8.18).

Fishing mortality rates at age (combined fleets) were high starting in about 1992 but have declined in the past years (Table A8.29 and Figure A8.17). To evaluate the potential for alternative "regimes", stock recruitment curves were estimated over different periods (as defined in Annex 4 of SC1). Within the current period (2001-2015), the level of expected recruitment was lower than the alternatives although recruitment has increased in recent years to about the long-term average mean. Time series of quantities derived by the model are presented in Table A8.30. Short, medium and long-term SSB predictions using Model 1.00 (single-stock hypothesis) are presented in Table A8.31.

The JJM assessment model was also run under the 2-stock hypothesis, and a summary figure of the northern (far-north) and southern stocks can be found in Figure A8.19. Conditions of the Jack mackerel stock in its entire distribution range in the southeast Pacific shows a continued recovery since the timeseries low in 2010. It is noted that under the two-stock model, the northern unit shows stable and relatively low biomass over the last decade, while the southern unit shows an increasing trend. The southern unit showed similar results to that of the single-stock hypothesis, although SSB was estimated slightly higher under the former scenario. Estimates of stock size and exploitation rate for the Northern stock were comparable to previous years and show a small increase in stock size in the last year while fishing mortality is low (Figure A8.19).

## 5. Management Advice

New data and indicators on the status of the Jack mackerel stock suggest that conditions evaluated in detail from the last benchmark assessment (completed in 2018) are relatively unchanged. The population trend is estimated to be increasing. The indications of stock improvement (higher abundance observed in the acoustic survey in the northern part of Chile, better catch rates apparent in some fisheries, and increase in average age in the Chilean fisheries) drive the increase.

Historical fishing mortality rates and patterns relative to the provisional biomass target are shown in Figure A8.17. Near term spawning biomass is expected to increase from the 2019 estimate of 6.2 million $t$ to 7.5.1 million $t$ in 2020 (with approximate $90 \%$ confidence bounds of $6.0-9.2$ million $t$ ).

Given current stock status, the third tier of the Jack mackerel rebuilding plan should be applied. However as this would result in a potential increase in the catch of over 480 kt a maximum increase of $15 \%$ needs to be applied in line with the "adjusted Annex K" rebuilding plan. This would result in a 2020 catch level for Jack mackerel within the entire Jack mackerel range to be at or below 680 kt . Note that this stock status is based on an assessment configuration that assumes a constant 5.5 million $t B_{M S Y}$ level. Recent increases in the theoretical $B_{M S Y}$ values (estimated in the model; likely due to changes in selectivity of all fisheries combined; different from the constant $B_{M S Y}$ ) would imply an estimate of SSB at about $40 \%$ over $B_{M S Y}$. Under the current harvest control rule, a $15 \%$ increase results in recommended catch levels at or below 680 kt .

Projections show a high likelihood of the biomass being rebuilt to $\mathrm{B}_{\text {MSY }}$ in 2019 under the most conservative recruitment productivity scenario evaluated. As such, a re-evaluation of the rebuilding plan is recommended to analyse sustainable exploitation rates of a re-built Jack mackerel stock.

## 6. Assessment Issues

Based on results from the 2018 assessment workshop, as noted previously, assessment plans for 2020 should be developed several months prior to SC8 (or the next benchmark) so that data coordinators can configure alternatives and conduct a careful evaluation of all available information to best guide the Commission. One of the higher priority items for consideration continues to be the catch-at-age estimates (based on age-determinations being conducted from different labs) and mean body weights at age assumed in the model. Another priority for consideration is the development of guidelines for standardisation of CPUE indices and the collection of relevant data. Results of the data weighting and the retrospective pattern analysis also warrant further investigation.

The issue of evaluating sensitivities to the early fishery age composition data was raised. The SC noted that this might be a fruitful avenue for investigation in subsequent assessments, particularly since these data (pre-1990) are less well-documented.

Table A8.5. Catch at age for fleet 4. Units are relative value (they are normalised to sum to 100 for each year in the model). Green shading reflects relative level. Catch-at-age 1979-2013 were calculated considering Age-Length Key from fleet 2. Catch-at-age 2017 was calculated with an Age-Length Key from Chile from the EU.

Age group (years)

Legend:
Chile (1): Acoustics for south-central zone in Chile
Chile (2): Acoustics for northern zone in Chile
Chile (3): Chilean south-central fishery CPUE for fleet 1
Chile (4): Daily Egg Production Method
Peru(1): Peruvian acoustic index in fleet 3
Peru(2): Peruvian echo-abundance index in fleet 3 (alternative)
Peru(3): Peruvian fishery CPUE in fleet 3
China: Chinese CPUE for fleet 4 (down weighted)
Offshore: Combined CPUE for China, EU, South Korea, Russia, and Vanuatu in fleet 4

Table A8.11. Jack mackerel sexual maturity by age used in the JJM models.

| Age (yr) | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Single Stock | 0.070 | 0.310 | 0.720 | 0.930 | 0.980 | 0.990 | 1.000 | 1.000 | 1.000 | 1.000 | 1.000 | 1.000 |
| Far North <br> Stock | 0.000 | 0.370 | 0.980 | 1.000 | 1.000 | 1.000 | 1.000 | 1.000 | 1.000 | 1.000 | 1.000 | 1.000 |

Table A8.12. Jack mackerel growth and natural mortality parameters used in JJM models.

## Parameter Far North stock Single stock

| $L_{\infty}(\mathrm{cm})$ (Total length) | 80.4 | 74.4 |
| :---: | :---: | :---: |
| $k$ | 0.16 | 0.16 |
| $L_{0}(\mathrm{~cm})$ | 18.0 | 18.0 |
| $M$ year $\left.^{-1}\right)$ | 0.33 | 0.23 |

$L_{0}$ is the mean length at the recruitment age (1 yrs).

Table A8.13. Ageing error matrix of Jack mackerel.

|  | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | $12+$ |

Table A8.18. Years and types of information used in the JJM assessment models.
$\left.\left.\begin{array}{|l|c|c|c|c|c|c|}\hline \text { Fleet } & \text { Catch-at-age } & \text { Catch-at-length } & \text { Landings } & \text { CPUE } & \text { Acoustic } & \text { DEPM } \\ \hline \begin{array}{l}\text { North Chile } \\ \text { purse seine }\end{array} & \text { 1975-2019 } & & & & & \begin{array}{c}\text { Index: 1984- } \\ \text { 1988; 1991; } \\ \text { 2006-2019 }\end{array} \\ \text { Age comps: 2006- } \\ \text { 2019 }\end{array}\right] \begin{array}{c}\text { Index: 1999- } \\ \text { 2008 comps: } \\ \text { 2001-2008 }\end{array}\right]$
(*) Are converted to age using age-length keys of central-southern area off Chile

Table A8.19. Symbols and definitions used for model equations.

| General Definitions | Symbol/Value | Use in Catch at Age Model |
| :---: | :---: | :---: |
| Year index: $i=\{1970, \ldots ., 2019\}$ | I |  |
| Fleets (f) and surveys (s) | $f, s$ | Identification of information source |
| Age index: $j=\left\{1,2, \ldots, 12^{+}\right\}$ | $J$ |  |
| length index: $/=\{10,11, \ldots, 50\}$ <br> Mean length at age <br> Variation coefficient the length at age <br> Mean weight in year $t$ by age $j$ | $\begin{gathered} \hline l \\ L_{j} \\ c v \\ W_{t, j} \end{gathered}$ |  |
| Maximum age beyond which selectivity is constant | Maxage | Selectivity parameterisation |
| Instantaneous Natural Mortality | M | Constant over all ages |
| Proportion females mature at age $j$ | pj | Definition of spawning biomass |
| Ageing error matrix | T |  |
| Proportion of length at some age Sample size for proportion in year $i$ | $\begin{aligned} & \bar{\Gamma} \\ & T_{i} \end{aligned}$ | Transform from age to length Scales multinomial assumption about estimates of proportion at age |
| Survey catchability coefficient | $q^{s}$ | $\text { Prior distribution = lognormal( } \left.\mu_{q,}^{s} \sigma_{q}^{2}\right)$ |
| Stock-recruitment parameters | $R_{0}$ | Unfished equilibrium recruitment |
|  | $h$ | Stock-recruitment steepness |
|  | $\sigma_{R}^{2}$ | Recruitment variance |
| Unfished biomass | $\varphi$ | Spawning biomass per recruit when there is not fishing |
| Estimated parameters |  |  |
| $\phi_{i}(\#), R_{0}, h, \varepsilon_{i}(\#), \mu^{f}, \mu^{s}, M, \eta_{j}^{s}(\#), \eta_{j}^{f}(\#), q^{s}(\#)$ |  |  |

Note that the number of selectivity parameters estimated depends on the model configuration.

Table A8.20. Variables and equations describing implementation of the joint Jack mackerel assessment model (JJM).

| Eq | Description | Symbol/Constraints | Key Equation(s) |
| :---: | :---: | :---: | :---: |
| 1) | Survey abundance index (s) by year. The symbol $\Delta^{s}$ represents the fraction of the year when the survey occurs. | $I_{i}^{s}$ | $I_{i}^{s}=q^{s} \sum_{j=1}^{12} N_{i j} W_{i j} S_{j}^{s} e^{-\Delta^{s} Z_{i j}}$ |
| 2) | Catch biomass by fleet ( $f=1,2,3,4$ ), year(i) and age (j) /length (I) <br> (transformation from age to length composition. Fleet 3, FarNorth) | $\hat{C}_{i l}, \hat{C}_{i j}, \hat{Y}_{i}$ | $\begin{aligned} & \hat{C}_{i, j}^{f}=N_{i, j} \frac{F_{i, j}^{f}}{Z^{f}{ }_{i, j}}\left(1-e^{-Z^{f}{ }_{i, j}}\right) \\ & \widehat{\mathrm{Y}}_{i}{ }_{i}=\sum_{j=1}^{12+} \hat{C}_{i, j}^{f} w_{i, j}^{f} \\ & \hat{C}_{i l}=\Gamma \hat{C}_{i j} \\ & \Gamma_{l, j}=\int_{j}^{j+1} e^{-\frac{1}{2 \sigma_{j}^{2}}\left(l-L_{j}\right)^{2}} d l \\ & L_{j}=L_{00}\left(1-e^{-k}\right)+e^{-k} L_{j-1} \\ & \sigma_{j}=c v L_{j} \end{aligned}$ |
| 3) | Proportion at age j, in year i <br> Proportion at length I, in year i |  | $\begin{aligned} & p_{i j}^{f}=\frac{\hat{C}_{i j}^{f}}{\sum_{j} \hat{C}_{i j}^{f}} p_{i j}^{s}=\frac{N_{i j} S_{j}^{s} e^{-\Delta^{s} Z_{i j}}}{\sum_{j} N_{i j} S_{j}^{s} e^{-\Delta^{\Delta} Z_{i j}}} \\ & P_{i l}=\frac{C_{i l}}{\sum_{l=10}^{50} C_{i l}} \end{aligned}$ |
| 4) | Initial numbers at age | j = 1 | $N_{1970, j}=e^{\mu_{R}+\varepsilon_{1970}}$ |
| 5) |  | $1<\mathrm{j}<11$ | $N_{1970, j}=e^{\mu_{R}+\varepsilon_{1971-j}} \prod_{j=1}^{j} e^{-M}$ |
| 6) |  | $\mathrm{j}=12+$ | $N_{1970,12+}=N_{1970,11} e^{-M}\left(1-e^{-M}\right)^{-1}$ |
| 7) | Subsequent years (i>1970) | $\mathrm{j}=1$ | $N_{i, 1}=e^{\mu_{R}+\varepsilon_{i}}$ |
| 8) |  | $1<\mathrm{j}<11$ | $N_{i, j}=N_{i-1, j-1} e^{-Z_{i-1, j-1}}$ |
| 9) |  | $j=12+$ | $N_{i, 11^{+}}=N_{i-1,11} e^{-Z_{i-1,10}}+N_{i-1,12} e^{-z_{i-1,11}}$ |
| 10) | Year effect and individuals at age 1 and $i=1958, \ldots, 2019$ | $\varepsilon_{i}, \sum_{i=1958}^{2018} \varepsilon_{i}=0$ | $N_{i, 1}=e^{\mu_{R}+\varepsilon_{i}}$ |

| Eq | Description | Symbol/Constraints | Key Equation(s) |
| :---: | :---: | :---: | :---: |
| 11) | Index catchability <br> Mean effect <br> Age effect | $\eta^{s}{ }_{j}, \sum_{j=1958}^{2018} \eta^{s}{ }_{j}=0$ | $\begin{array}{ll} q_{i}^{s}=e^{\mu^{s}} & \\ s_{j}^{s}=e^{\eta_{j}^{s}} & j \leq \text { maxage } \\ s_{j}^{s}=e^{\eta_{\text {maxage }}^{s}} & j>\text { maxage } \end{array}$ |
| 12) | Instantaneous fishing mortality |  | $F_{i j}^{f}=e^{\mu^{f}+\eta_{j}^{f}+\phi_{i}}$ |
| 13) | Mean fishing effect | $\mu^{f}$ |  |
| 14) | Annual effect of fishing mortality in year i | $\varphi_{i}, \sum_{i=1970}^{2018} \varphi_{i}=0$ |  |
| 15) | age effect of fishing (regularised) In year time variation allowed <br> In years where selectivity is constant over time | $\begin{gathered} \eta^{f}{ }_{j}, \sum_{j=1958}^{2018} \eta_{j}^{f}=0 \\ \eta_{i, j}^{f}=\eta_{i-1, j}^{f} \end{gathered}$ | $\begin{array}{ll} s_{i j}^{f}=e^{\eta_{j}^{f}} & j \leq \text { maxage } \\ s_{i j}^{f}=e^{\eta_{\text {maxage }}^{f}} & j>\text { maxage } \end{array}$ <br> $i \neq$ change year |
| 16) | Natural Mortality | M | fixed |
| 17) | Total mortality |  | $Z_{i j}=\sum_{f} F_{i j}^{f}+M$ |
| 17) | Spawning biomass (note spawning taken to occur at mid of November) | $B_{i}$ | $B_{i}=\sum_{j=2}^{12} N_{i j} e^{-\frac{10,5}{12} Z_{i j}} W_{i j} p_{j}$ |
| 18) | Recruits (Beverton-Holt form) at age 1. | $\tilde{R}_{i}$ | $\begin{aligned} & \tilde{R}_{i}=\frac{\alpha B_{t}}{\beta+B_{i}}, \\ & \alpha=\frac{4 h R_{0}}{5 h-1} \text { and } \beta=\frac{B_{0}(1-h)}{5 h-1} \text { where } \mathrm{h}=0.8 \\ & B_{0}=R_{0} \varphi \\ & \varphi=\sum_{j=1}^{12} e^{-M(j-1)} W_{j} p_{j}+\frac{e^{-12 M} W_{12} p_{12}}{1-e^{-M}} \end{aligned}$ |

Table A8.21 Specification of objective function that is minimised (i.e., the penalised negative of the log-likelihood).

|  | Likelihood /penalty component |  | Description / noted |
| :---: | :---: | :---: | :---: |
| 19) | Abundance indices | $L_{1}=0.5 \sum_{s} \frac{1}{c v_{s}^{2}} \sum_{i} \log \left(\frac{I_{i}}{\hat{I}_{i}}\right)^{2}$ | Surveys / CPUE indexes |
| 20) | Prior on smoothness for selectivities | $L_{2}=\sum_{l} \lambda_{2} \sum_{j=1}^{12}\left(\eta_{j+2}^{l}+\eta_{j}^{l}-2 \eta_{j+1}^{l}\right)^{2}$ | Smoothness (second differencing), Note: $l=\{s$, or $f\}$ for survey and fishery selectivity |
| 21) | Prior on recruitment regularity | $\begin{gathered} L_{3}=\lambda_{3} \sum_{i=1958}^{2018} \varepsilon^{2}{ }_{i} \\ \lambda_{3}=\frac{0.5}{\sigma_{R}^{2}} \end{gathered}$ | Influences estimates where data are lacking (e.g., if no signal of recruitment strength is available, then the recruitment estimate will converge to median value). |
| 22) | Catch biomass likelihood | $L_{4}=0.5 \sum_{f} \frac{1}{c v_{f}^{2}} \sum_{i=1970}^{2018} \log \left(\frac{Y_{i}^{f}}{\hat{Y}^{f}{ }_{i}}\right)^{2}$ | Fit to catch biomass in each year |
| 23) | Proportion at age/length likelihood | $L_{5}=-\sum_{v, i, j} n^{v} P_{i, j / l}^{v} \log \left(\hat{P}_{i, j / l}^{v}\right)$ | $v=\{s, f\}$ for survey and fishery age composition observations $P_{i, j / l}$ are the catch-at-age/length proportions n effective sample size |
| 24) | Dome-shaped selectivity | $\begin{aligned} & L_{6}=\lambda_{4} \sum_{j=6}^{12}\left(\ln S_{j-1}-\ln S_{j}\right)^{2} \\ & S_{j-1}>S_{j} \end{aligned}$ | (relaxed in final phases of estimation) |
| 25) | Fishing mortality regularity | F values constrained between 0 and 5 | (relaxed in final phases of estimation) |
| 26) | Recruitment curve fit | $\begin{aligned} & L_{7}=\lambda_{5} \sum_{j=1970}^{2015} \log \left(\frac{N_{i, 1}}{\tilde{R}_{i}}\right)^{2} \\ & \lambda_{5}=\frac{0.5}{\sigma_{R}^{2}} \end{aligned}$ | Conditioning on stock-recruitment curve over period 1970-2015. <br> (Model 1.00 used the period 20002016) |
| 27) | Priors or assumptions | $R_{0}$ non-informative | $\sigma_{R}=0.6$ |
| 28) | Overall objective function to be minimised | $\dot{L}=\sum_{k} L_{k}$ |  |

Table A8.22. Coefficients of variation and sample sizes used in likelihood functions, with adjustments based on calculated Francis weights. Initial sample sizes are in parentheses.

| Abundance index | cv | Catch biomass likelihood | cv |

| CPUE - Offshore | 100 |  |  |
| Smoothness for selectivities (fleets) | $\lambda$ | Proportion at age (or length) likelihood | n |
| N -Chile | 1 | N -Chile | 5.37 (20) |
| CS-Chile | 25 | CS-Chile | 4.07 (50) |
| Farnorth | 12.5 | Farnorth (length) | 30 |
| Offshore | 12.5 | Offshore | 26.1 (30) |
| Recruitment regularity | $\lambda$ | $S$ - Recruitment curve fit | cv |
|  | 1.4 |  | 0.6 |

Table A8.23. Description of JJM model components and how selectivity was treated (two-stock hypothesis; Far North Stock).

| Item | Description | Selectivity assumption |
| :--- | :--- | :--- |
| Fisheries |  |  |
| 1) Peruvian and Ecuadorian area fishery | Selectivity in the model under the two-stock <br> hypothesis was estimated from length composition <br> data (converted to age inside the model). Two time <br> blocks were considered - before and after 2002. This <br> is a different assumption than mod1.00 (one-stock), <br> which has annual variations in selectivity between <br> 1981 and 2019. |  |

## Index series

| 2) | Acoustic survey in Peru | Assumed to be the same as in fishery 1) |
| :--- | :--- | :--- |
| 3) | Peruvian fishery CPUE | Assumed to be the same as in fishery 1) |

Table A8.24. Description of JJM model components and how selectivity was treated (two-stock hypothesis; South stock).

| Item | Description | Selectivity assumption |
| :---: | :--- | :--- |
| Fisheries |  |  |
| 1) | Chilean northern area fishery | Estimated from age composition data. Annual variations were |
|  |  | considered since 1984 |
| 2) | Chilean central and southern | Estimated from age composition data. Annual variations were |
|  | area fishery | considered since 1984. |
| 3) | Offshore trawl fishery | Estimated from age composition data. Annual variations were |
|  |  | considered since 1980. |

| x |  |  |
| :---: | :---: | :---: |
| 4) | Acoustic survey in central and southern Chile | Estimated from age composition data. Two time-blocks were considered 1970-2004; 2005-2009. |
| 5) | Acoustic survey in northern Chile | Estimated from age composition data. Selectivity changes were implemented in 2012 and 2016. |
| 6) | Central and southern fishery CPUE | Assumed to be the same as 2) |
| 7) | Egg production survey | Estimated from age composition data. Two time-blocks were considered 1970-2002; 2003-2008. |
| 8) | Chinese fleet CPUE (from FAO workshop; down-weighted in SC7 after incorporation into the Offshore CPUE) | Assumed to be the same as 3) |
| 9) | Offshore fleet (China, EU, Korea, Russia, Vanuatu) CPUE | Assumed to be the same as 3) |

| Table A8.25. | Description of JJM model components and how selectivity was treated under the single stock hypothesis. |  |
| :---: | :--- | :--- |
| Item | Description | Selectivity assumption |
| Fisheries |  |  |
| 1) | Chilean northern area fishery | Estimated from age composition data. Annual variations were |
|  |  | considered since 1984 |
| 2) | Chilean central and southern | Estimated from age composition data. Annual variations were |
|  | area fishery | considered since 1984. |
| 3) | Peruvian and Ecuadorian area | Estimated from length composition data (converted to age |
|  | fishery | inside the model). Annual variations were considered since |
|  |  | 1981 |
| 4) | Offshore trawl fishery | Estimated from age composition data. Annual variations were |
|  |  | considered since 1980. |

## Index series

5) Acoustic survey in central and Estimated from age composition data. Two time-blocks were southern Chile considered 1970-2004; 2005-2009.
6) Acoustic survey in northern Chile
7) Central and southern fishery CPUE
8) Egg production survey
9) Acoustic survey in Peru
10) Peruvian fishery CPUE
11) Chinese fleet CPUE Assumed to be the same as 4) Estimated from age composition data 2006-2016. Selectivity changes were implemented in 2015 and 2016
Assumed to be the same as 2)

Estimated from age composition data 2001, 2003-2006, 2008. Two time-blocks were considered around 2003.

Assumed to be the same as 3)
Assumed to be the same as 3)
12) Offshore fleet (Vanuatu, Russia, Assumed to be the same as 4) Korea, EU \& China) CPUE

Table A8.26. Systematic model progression from the 2019 assessment data to the agreed revised datasets for 2019. Note that the data file names corresponding to each model follow the convention e.g., "Mod0.01.dat" and "Mod0.01.ctl". The same process was repeated for the model under the 2-stock hypothesis.

| Model | Description |
| :---: | :---: |
| Models 0.x | Data introductions |
| mod0.00 | Exact 2018 model and data set through 2018 (mod1.4 from SC06) |
| mod0.01 | Data file as 0.0 with revised catches through 2018; 2018 model |
| mod0.02 | As 0.01 but with updated fishery age compositions and weight-at-age for $N$ _Chile, SC_Chile, and Offshore_Trawl to 2018 |
| mod0.03 | As 0.02 but with updated fishery length compositions for FarNorth to 2018 |
| mod0.04 | As 0.03 but with updated FarNorth (Peru) CPUE index to 2018 |
| mod0.05 | As 0.04 but with updated Offshore CPUE index to 2018; removed 2006-2007; downweighted Chinese_CPUE (CV=10; now combined into Offshore CPUE) |
| mod0.06 | As 0.05 but with updated age comps and weight-at-age for Chile_AcousN to 2018 |
| mod0.07 | As 0.06 but with projected 2019 catch estimates |
| mod0.08 | As 0.07 but with updated fishery age composition and weight-at-age for N_Chile and SC_Chile to 2019 |
| mod0.09 | As 0.08 but with updated FarNorth CPUE to 2019 |
| mod0.10 | As 0.09 but with updated Acous_N survey index to 2019 |
| mod0.11 | As 0.10 but with updated age composition data from Acous_N to 2019 |
| mod0.12 | As 0.11 but with updated Chile CPUE (cpue_abs) |
| mod0.13 | As 0.12 but with updated Chile CPUE weight-at-age |
| mod0.14 | As 0.13 but with updated Peru CPUE weight-at-age |
| mod0.15 | As 0.14 but with updated Offshore CPUE weight-at-age |
| mod0.16 | As 0.15 but with updated FarNorth length composition data (to 2019) |
| mod0.17 | As 0.16 but with averaged weight-at-age data for 2015 SC_Chile (avg(2014,2016)), and $2015(\operatorname{avg}(2014,2016))$ and 2018/2018 (avg(2014,2016,2017)) Offshore |
| mod0.18 | As 0.17 but with downweighted (/10) age composition data for 2015 SC_Chile, and 2015+2018 Offshore |

Models 1.x Configuration sensitivities
mod1.00 As mod0.17 data file but model (i.e., selectivity changes) updated to 2019
mod1.00.ll As mod1.00 but low steepness and long recruitment time series (1970-2015)
mod1.00.Is As mod1.00 but low steepness and short recruitment time series (2000-2015)
mod1.00.hl As mod1.00 (i.e., high steepness and long recruitment time series (1970-2015))
mod1.00.hs As mod1.00 but high steepness and short recruitment time series (2000-2015)

Table A8.27. Spawning biomass of Jack mackerel (Mod 1.00; single-stock) obtained in previous SPRFMO SC meetings.

## 9. Figures

Figure A8.1. Catch of Jack mackerel by fleet. Green is the SC Chilean fleet, black is the offshore trawl fleet, red is the farnorth fleet, and blue in the northern Chilean fleet.

Figure A8.2. Model retrospective of spawning biomass (top) and recruitment (bottom) from 5 separate model runs, based on Model 1.00 (single-stock hypothesis).

Figure A8.3. Historical retrospective of spawning stock biomass, fishing mortality, and recruitment (2019 estimates from Model 1.00 (single-stock hypothesis)), as estimated and used for advice from past (and present) SPFRMO scientific committees.

Figure A8.4. Historical retrospective of management reference points (2019 estimates from Model 1.00 (single-stock hypothesis)), as estimated and used for advice from past (and present) SPRFMO scientific committees. It is to be noted that the $B_{\text {MSY }}$ in this figure is dynamically estimated within the model, and hence is not fixed at the provisional 5.5 million tons.

Figure A8.5. Mean weights-at-age (kg) over time used for all data types in the JJM models. Different lines represent ages 1 to 12 .

Figure A8.6. Model 1.00 (single-stock hypothesis) fit to the age compositions for the Chilean northern zone fishery (Fleet 1). Bars represent the observed data and lines represent the model predictions.

Age fits SC_Chile_PS
Observed

Figure A8.7. Model 1.00 (single-stock hypothesis) fit to the age compositions for the South-Central Chilean purse seine fishery (Fleet 2). Bars represent the observed data and lines represent the model predictions.

Length fits FarNorth
Observed $\square$ Predicted •

Figure A8.8. Model 1.00 (single-stock hypothesis) fit to the length compositions for the far north fishery (Fleet 3). Bars represent the observed data and lines represent the model predictions.

Age fits Offshore_Trawl Observed $\square$ Predicted

Figure A8.9. Model 1.00 (single-stock hypothesis) fit to the age compositions for the offshore trawl fishery (Fleet 4). Bars represent the observed data and lines represent the model predictions.

Figure A8.10. Model 1.00 (single-stock hypothesis) fit to the age compositions for the S-Central Acoustic survey. Bars represent the observed data and lines represent the model predictions.

Age fits Chile_AcousN
Observed $\square$ Predicted

Figure A8.11. Model 1.00 (single-stock hypothesis) fit to the age compositions for the N Chilean acoustic survey (bottom). Bars represent the observed data and lines represent the model predictions.

197019801990200020102020970198019902000201020209701980199020002010202097019801990200020102020

Figure A8.12. Model 1.00 (single-stock hypothesis) fit to different indices. Vertical bars represent 2 standard deviations around the observations.

Figure A8.13. Mean age by year and fishery. Line represents the Model 1.00 (single-stock hypothesis) predictions and dots observed values with implied input error bars.

Figure A8.14. Mean age by year and survey. Line represents the Model 1.00 (single-stock hypothesis) predictions and dots observed values with implied input error bars.

Figure A8.15. Mean length by year in fleet 3 (Far North). Line represents the Model 1.00 (single-stock hypothesis) predictions and dots observed values with implied input error bars.

## Selectivity of the Fishery by Pentad

Figure A8.16. Estimates of selectivity by fishery over time for Model 1.00 (single-stock hypothesis) Each cell represents a 5year period.

Figure A8.17. Model 1.00—single-stock hypothesis—summary estimates over time showing spawning biomass (kt; top left), recruitment at age 1 (millions; lower left) total fishing mortality (top right) and total catch (kt; bottom right). Blue lines represent the provisional $\mathrm{B}_{\text {MSY }}$ (upper left) and dynamic estimates of $\mathrm{F}_{\text {MSY }}$ (upper right).

Fished vs. unfished biomass
Fished - Unfished

Figure A8.18. Model 1.00 (single-stock hypothesis) results for the estimated total biomass (solid line) and the estimated total biomass that would have occurred if no fishing had taken place, 1970-2019.

## Far North

Southern stock

Figure A8.19. Model 1.00 -two-stock hypothesis - summary estimates over time showing spawning biomass (kt; top left), recruitment at age 1 (millions; lower left) total fishing mortality (top right) and total catch (kt; bottom right) for the "Far North" stock (top set) and for the "Southern" stock (bottom set).
