Catch-at-age and Abundance-at-age Using New Criteria of Age Assignment

Chile

Catch-at-age and abundance-at-age for jack mackerel in Chile by using new criteria of age assignment.

By Christian Valero & Francisco Cerna.

Instituto de Fomento Pesquero (Fisheries Development Institute), Valparaíso, Chile.

August, 2021

Abstract

This report shows the progress status of age structure data series of the Chilean jack mackerel, based on validated age-length keys, that was changed according to the new ageing criteria. The results include 1) the commercial catch age structure from 1980 to 2020 by quarter and fleet; 2) the abundance by age group of acoustic surveys in fleet 1 area for 2006, 2007, 2009, from 2013 to 2020 and fleet 2 from 2001 to 2012, 2017, 2020. These age structure include the mean length and weight fish by age group.

Introduction

The joint-stock assessment model for Jack Mackerel (JJM) used for the South Pacific Regional Fisheries Management Organization (SPRFMO) integrates two age-structured fishery-dependent and one age-structured fishery-independent time series, both annually provided by Chile for fitting purposes. Those data series help for interpreting the age-vulnerability pattern of fishing fleets operating along the central-south and north, as the age-acoustic surveyed abundance at southern Chile, respectively.

Two studies were carried out to validate the age of jack mackerel and provide more exact age structures (Cerna et al. 2016; Araya et al. 2019). Analyzing the microstructure of the otoliths and other methods such as monitoring a strong annual class and radiocarbon bomb, they concluded that jack mackerel shows high somatic growth in the first and second year of life. These results suggest that the first and third growth rings, identified in the historical ageing criteria, are false. Based on these findings, it was necessary to modify the age structure of the jack mackerel catches and the abundances of the acoustic cruises, based on new age-length keys that included these changes. For more details of these results consult the paper SC8-JM07.

This report describes the details about the ageing structure series of commercial and acoustic survey of Chilean jack mackerel using new age-length key that were changed according to the new ageing criteria.

Methods

The individual age of Jack Mackerel has been estimated using standard skeletochronology techniques of whole and cross-sectioned otolith in which an opaque and translucent ring is identified and counted as an annual increase or annulus. Now using the new ageing criteria (SC8-JM07) changes were made in: 1) catch-at-age time series for the period 1980-2020, integrating geographic position, date of capture, fish fork length, and the size and radius (mm) of each otolith sampled ($n=194,485$); and 2) abundance's age-structured of the acoustic surveys for some years to northern (Fleet 1 area) and southern zone (Fleet 1 area) zone between 2001-2020 using ageing data series of 3,972 otoliths pairs.

Reconstruction of catches by age group

We estimated the catch at age structure of Jack Mackerel using age length keys coming from the validated criteria according to the procedures described in paper SC8-JM07. The age structure of the catch was estimated with the quarterly age-length keys constructed for each fleet in order to extrapolate the catch by length stratum to catch by age group. Once a key was available, then it was used to distribute the length samples by age groups. This is possible because it is assumed that the sample of aged fish and the sample of fish measured for length are simple random samples from the same population, thus the probability that a fish is of a particular age, have its length is the same in both samples. The sequence of steps to reconstruct the catch and abundance age structure is shown in figure 1.

The platform used to calculate the age structure is available in Rpubs script at: https://rpubs.com/Christian_Valero/615932.

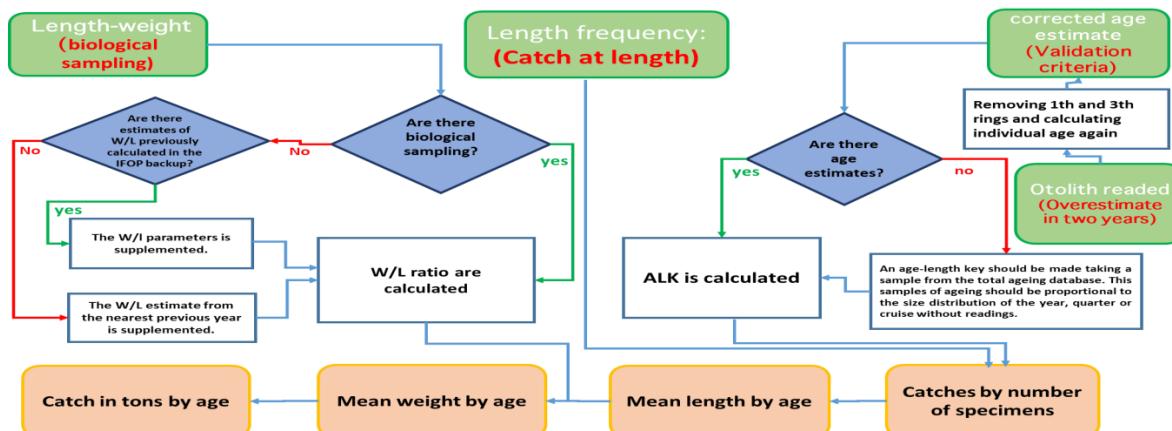

Figure 1. Diagram explaining the sequence of steps used for estimating the age structure.

Results

Reconstruction of commercial catches by age-group

The reconstruction of the catch age structure considered first the changes of otolith ageing data and second time were checking and validating of the lengths and biological's data for each of the quarters. This was possible to do for the period 1980-2020. This series was reconstituted with all the data: original, catch, length distribution and biological data for each year, quarter and fleet (Table 1 y 2).

Table 1. Catch by age group of the series 1980-2020 for the fleet 1, based in age-length key modified according new ageing criteria validated.

Reconstruction of acoustic surveys abundance by age-group

The same way that the catch age structure, the reconstruction of the abundances to the age considered first, the changes of otolith ageing data, and second, the checking and validating of the lengths and biological data of acoustic surveys. This was possible to do for the northern zone the years 2006, 2007, 2009, from 2013 to 2020 and southern zone from 2001 to 2012, 2017, 2020 (Table 3). This series did not have all ageing data, lacked original reading data from 2001 to 2004 in the southern zone and 2007 in the northern and southern zones. As the diagram indicates (Figure 1), in these cases a sample of 300 readings was taken from the ageing's total data of acoustic surveys, which was selected in proportion to the length frequency distribution of the year and zone without readings.

Table 3 Abundance by age group of acoustic survey's series for northern and southern zone, based on age-length key modified according new ageing criteria validated.

Discussion

Modification of the historic series from the new allocation criteria is supported by the evidence derived from the results of the validation of jack mackerel age with a multidisciplinary approach that included methods of daily micro increase, progression of strong year classes and radiocarbon bomb (Cerna et al. 2016, Araya et al. 2019, SC5-JM02, SC-04-JM-05, SC8-JM07, SC8-JM09).

The catch age structure was constituted by quarter for the series 1980 to 2020, using the age-length keys modified according to the new validated ageing criteria. The period before to 1980 could not be made due to the lack of information at a quarterly level, which would allow to make structures that are reliable.

The reconstruction of abundance age structure of the acoustic surveys has a preliminary character, since some data are missing and had to be replaced. However, this can be improved when the missing data becomes available.

The construction of catch age structure of the international fleet is still pending work. Although, these structure uses the age-length keys of Chile, in order to carry out this work we need to have the length frequency distribution of each year of this series that allows us to expand the catch by age group, data we understand could be available in the countries that contribute with these catches.
